FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

BRIEFS

POLISH-SOVIET AVIATION COOPERATION—In a period of three years, the joint Polish-Soviet design office developed and designed the world's first M-15 agricultural jet aircraft which has already undergone government testing in the USSR. In regard to cooperation between Polish and Soviet aviation industries, the Transportation Equipment Plants in Mielec, Swidnik and Kalisz are participating in the construction of the IL-86 aerobus which is a third-generation transport aircraft and is being produced by the Soviet aviation industry. In accordance with the agreement, Poland is to provide complete tail assemblies, engine-suspension strut assemblies, aerodynamic lift assemblies and other elements. A total of 15 tail assemblies for the IL-86 aerobus have been completed in 1980 at the Transportation Equipment Plants of the Polish Aviation Enterprises - Mielec. Another very important agreement, in which Poland is to initiate production of the light AN-28 passenger aircraft having short take-off and landing capability, was recently signed. Polish production of this aircraft will begin in 1984, and 1,200 of these aircraft will have been built for the USSR by the end of 1990. [Excerpt] [Warsaw RYNKI ZAGRANICZNE in Polish No 97, 12 Aug 80 p 8]

SOVIET-POLISH AVIATION DEVELOPMENTS—Many Polish passengers and much cargo are transported by foreign airlines which use, on long flights, only the wide-fuselage aircraft having more capacity and using half as much fuel as other aircraft. Similar aircraft may be expected on the Soviet market in 1985-1990. Up to this period, Polish domestic flights will be conducted with the currently used AN-24 aircraft, the IL-18 and TU-134 aircraft which are being gradually withdrawn from the foreign routes and the new JAK-42 aircraft whenever they are acquired. IL-62 aircraft will be used for long-range transport service, whereas the delivery of four IL-62M and five IL-86 aircraft is envisaged in 1981-1985. Therefore, the matter of equipment is one of the important airline requirements that is equal to other matters, such as the construction of the international airport at Okecie and the reconstruction and modernization of many Polish domestic airports or the expansion of technical facilities which are the worst in Europe. NEED TO IMPROVE EFFECTIVENESS OF AGRICULTURAL EXPENDITUPES

Tirana ZERI I POPULLIT in Albania 24 Jul 80 p 2

[Article by Gjon Gorishti, deputy chairman of the State Planning Commission: "Improvement of the Effectiveness of Expenditures in Agriculture"]

[Text] In the framework of the tasks assigned today for the present development of the economy and for the future, the improvement of the effectiveness of production in agriculture, as in all the other branches of material production, constitutes one of the important directions where the struggle, work and efforts of the government and economic organs must be concentrated, solving, correctly and on scientific bases, the problems that emerge in this field. In the coming five-year plan, according to preliminary calculations, the overall agricultural production is foreseen to be increased by about 41 percent, compared to that of the Sixth Five-Year Plan. With this increase and on the basis of the fact that the increase in agricultural production is expected to be provided mainly from the increase in the production of agricultural and livestock crops, the main requirement for the working collectives of the enterprises and agricultural cooperatives is to concentrate their attention and mobilization on the most complete activization possible of all the material, technical and socio-political factors that guarantee the fulfillment, one by one, of the tasks of the production plan.

Practice has shown that those agricultural units, which have fulfilled the tasks of the production plan in quantity and quality, have, at the same time, obtained great effectiveness in the use of the material base. In these conditions, the essential issue in improving effectiveness is to assure high yields, thus, rapidly progressing toward their transformation into modern units of socialist production, where the work and management will be achieved on more healthy scientific bases.

To fulfill the targets of the coming five-year plan in agriculture, as was stressed at the Eight Plenum of the Party Central Committee, it is required that science and scientific research works be expanded and executed broadly in all agricultural units. This, first of all, sets forth the necessity to rigorously execute the agro-zootechnical code and the generalization, dissemination and execution of progressive experience obtained in practice

by many agricultural enterprises and cooperatives, as well as to struggle for continually reducing production costs per unit of production. These and other measures for perfecting the management and organization of work are the more important guidelines to guarantee the increase of agricultural production at high rates, on the one hand, and to use, with calculation and great effectiveness, the vigorous work and material values that constitute expenditures for production, on the other hand.

There are great reserves in agriculture for increasing its production and improving its effectiveness. There are many work brigades, agricultural units and districts which are waging a comprehensive and continuous struggle for obtaining the maximum production possible from the land on the basis of the rational utilization with high effectiveness of the technical-material base. In 1979 in Lushnje and Fier districts, for every kilogram of active substance chemical fertilizer 7 and 8.5 kilograms of wheat were produced respectively. However, this result was not obtained in Durres and Kruje districts although they have comparable conditions. The produced 5 and 6.4 kilograms respectively. Similarly, Librazhd District produced 7.2 kilograms of wheat for one kilogram of active substance fertilizer, while Skraper District produced only 4.7 kilograms of wheat.

There are many districts and agricultural units which, because of the failure to use chemical fertilizers with correct and scientific criteria, because of the failure to rely on the agro-pedological studies of the lands and because of the failure to accompany them with the activization, at the required level, of all the other factors that increase production and output, did not manage to provide correct relationships between the increase of expenditures for chemical fertilizers and the overall agricultural production. Thus, in Vlore District, expenditures for chemical fertilizers in 1979, compared to 1975, were increased by about 75 percent, while overall agricultural production was increased by only 4 percent; or, in Durres District where expenditures for chemical fertilizers were increased by 97 percent and where there was an increase of agricultural production of only 15 percent.

The analysis of the factors and roads that lead to the improvement of expenditures of agricultural production and the measures which will be taken in this field must aim at increasing the revenues for every 100 leks of production expenditures. In this regard, it is necessary to keep in mind that the improvement of the effectiveness of expenditures does not mean that the expenditures needed for fulfilling production must be limited. The problem is that, with the planned expenditures, the continual increase of agricultural and livestock production, of yields and of revenues must be made possible. In this regard, the good organization of work for the systematic monitoring of production expenditures in relation to production and revenues is of special importance.

The practice of recent years shows that, in this direction, violations have been permitted and, sometimes even important violations have been committed

with consequences for the enterprises and agricultural cooperatives. In some districts and specific agricultural units there also are trends showing that, while material expenditures are increased from one year to the other, above the stipulated tasks, they are not always accompanied by an increase of agricultural production and, in certain cases, they are even accompanied by a decrease of agricultural production. Thus, while in 1975 the agricultural cooperatives in Tirana District had 37 leks of material expenditures for 100 leks of agricultural production, in 1979 they had 45 leks, and, in Shkoder District expenditures went from 28 leks in 1975 to 34 leks, and in Vlore District expenditures increased from 25 leks to 40 leks and so forth. In 1979 the agricultural cooperatives in Kruje and Fier districts did not achieve the increase of agricultural production in accordance with the plan tasks; they fulfilled production expenditures by 101 percent and 108 percent respectively and so forth.

The great possibilities of agricultural cooperatives for improving the effectiveness of production are also evident in the fact that, between the districts with comparable conditions, there are different levels of revenues compared to the material expenditures that are made. Thus, while Korce and Berat districts obtained 227 and 267 leks of revenues respectively for 100 leks of expenditures, Kruje and Lushnje districts obtained 205 and 216 leks respectively.

The continual analysis of the progress made in these fields by agricultural units and districts and the determining and execution of the technical and organizational measures for fulfilling the production tasks with the expenditures that are earmarked, for carrying out a bitter struggle for applying regulations, for the proper handling of yields and for the elimination of damages, especially during the grain harvesting and threshing campaigns and for improving the quality of agricultural and livestock products and so forth are tasks that require a greater concern on the part of all agricultural units. An important role in this field must be played by the planning and finance organs in the districts and agricultural units.

The high rates that must be achieved in the development of agriculture and the effectiveness of production are linked with the use of live labor in accordance with the correct rules of work and with the rational use of chemical and organic fertilizers and of the other material expenditures, harmonizing them with all the requirements of the agro-zootechnical Code that guarantee the obtaining of the planned yields. The task is assigned on the basis of deep analyses to discover not only the shortcomings and weaknesses in the practice of the organization and management of production, but also to determine the most effective measures for eliminating them, in order that production expenditures will give the results required for increasing production and yields.

In this field, it is required that, in every production unit and area, the needs for expenditures, live labor and materialized work, must be calculated and planned as correctly as possible and on the basis of established

norms, taking into consideration the tasks stipulated for increasing production. Also, it is necessary that, both in the process of the drafting of the plan and in the process of its fulfillment, correct relationships be maintained between the factors that determine the effectiveness of production expenditures, especially the relationships between production and the working people, between norms for accumulation and consumption, between net revenues and production expenditures and between the investments used in the production sphere and those used in the non-productive sphere and so forth. These matters and others that emerge are objects of thorough studies and discussions in which technical and economic ideas must steep in agricultural units, making them the problems of the working collectives; the concrete ways and measures for achieving the best results possible must be determined.

For this, it is necessary that specialists and cadres in agricultural units must increase their attention and care not only during the process of the drafting of the plan, but also and especially during the fulfillment of stipulated tasks, since, often, in this field, the most accentuated weaknesses and shortcomings are observed. Specific tasks are assigned to the economists in the planning and finance sectors so that they will further delve into and better connect themselves with these problems, in order to respond to the tasks set forth by the Eight Plenum of the Party Central Committee. They must face these matters with more expanded studies and analyses and, time after time, they must make them the problems of the working collectives, expressing themselves more loudly not only in regard to the situation, but also in regard to the roads which they must take, because, this is the way to further improve their role in the planned management of the economy.

The most recent plenums of the party Central Committee assigned important tasks for improving the effectiveness of social production in the various branches of the economy. The assurance of high profitability, as the main road to increase socialist accumulation and to maintain high rates in the development of the economy in our country makes it necessary for all the links of the economy to thoroughly understand the party recommendation that the plan is not production alone, but also yields, cost, quality and all the other factors that make it possible to fulfill the production tasks with as few expenditures as possible, in order to further improve their economic effectiveness.

OVERSPENDING BY ENTERPRISES CRITICIZED BY BANK DIRECTOR

Tirana ZERI I POPULLIT in Albanian 28 Jun 80 p 3

[Article by Kostaq Postoli, director general of the State Bank: "Strengthening Monetary Circulation Requires Rythmic Fulfillment of Planned Tasks"]

[Text] In 1979 and in the first four months of this year, several improvements were accomplished in the field of monetary circulation. A good rapport was maintained among various indicators related to the demands of the economic law of monetary circulation. The circulation of goods by cash in 1979 increased 3.6 percent. The domestic trade enterprises fulfilled the plan for goods circulation nearly 100 percent in the four month period as well.

The work of financial and bank organs has its own influence on these fine results. However, analyzing this work under the light of the materials of the Seventh Plenum of the Party Central Committee and the recommendations of Comrade Enver Hoxha, these achievements stimulate us to move on ahead, to improve our work further and to make the bank a strong organ of control by means of the lek over the economic and financial activity of agricultural enterprises and cooperatives. The goal is to increase production and accumulation, to strengthen the savings system and to improve the effectiveness of spending.

The annual deficit last year in the circulation of goods at commercial enterprises in such districts as Berat, Tepelene, etc., represents only a one- to two-day turnover. At Tropoje, however, the plan was underfulfilled by only 77,000 leks, or by three to four hours work in the trade network. This indicates a lack of specific knowledge of the situation, no operational following of tasks, poor discipline and lack of responsibility in fulfillment of the plan's indicators. The district branches of the State Bank daily follow the dianamic of the fulfillment of goods circulation by cash, they often inspect the condition of goods in warehouses and in circulation, they uncover shortcomings and deficiencies in the organization of the work for the distribution of goods, etc. However, these phenomena are but noted and are not used properly to have an effective influence on the fulfillment of planned tasks.

It is a fact that a good part of the deficits in the implementation of contracts has been created by intradistrict trade between producing enterprises and agricultural cooperatives. This indicates that the influence and assistance of financial sections and bank branches have been inadequate. Moreover, when an accounting is demanded on the fulfillment of contracts, deficits are immediately pointed out by other districts, while the deficits created by agricultural enterprises or cooperatives within the same district are passed over superficially, tacitly and with justification. This is wrong. The financiers should not remain indifferent when they spot shortcomings and weaknesses but should study and analyze them, bring out the causes, specify the steps and ways to correct them and point them out in time to the district party and government organs.

In cooperation with sections of the executive committee of the district people's council and the commercial enterprises, the State Bank should make better and more effective use of the confrontation method between producing enterprises within and without the district, in conjunction with the government organs and bank branches of other districts, to follow production fulfillment (in terms of quantity, assortment and quality) and its distribution to consumer enterprises. This cooperation will become stronger especially in conjunction with the study of the people's purchasing power for each region and for the distribution and redistribution of stocks of goods consistent with it. The district branches of the State Bank have made analyses of regional purchasing power, however these should be put to better use by the commercial enterprises, taking measures for a more accurate distribution and redistribution of stocks of goods, which will also have an effect on the accomplishment of the goods circulation plan. We say this because the stocks of goods planned by a number of commercial enterprises are not detailed for each unit and as a result their distribution is not carried out with rigid discipline and surplus goods exist in some areas at a time when they are lacking in others. Likewise, to achieve good results in fulfilling the goods circulation plan, steps need to be taken to accomplish the production plan tasks and to carry out contracts. Otherwise, the goods circulation plan will not be fulfilled, the needs of the people will not be met properly and, as a consequence, irregularities are created in monetary circulation.

Problems also exist in fulfilling the goods circulation plan at agricultural cooperatives. Such districts as Tirana, Berat, Gjirokaster, Lushnja, etc. had the same level of goods circulation at agricultural cooperatives in 1979 as in 1978, even though the wage fund increased. The plan was fulfilled 92.4 percent in the first four months of this year. With the exception of Korca and Mirdita districts, other districts had considerable deficits, especially Mat, Elbasan, Shkoder, Gjirokaster, Tepelene, Vlore, Lezhe, etc. In this direction, the financial and banking organs are not sufficiently concerned or involved, and the necessary attention is not being paid to the accomplishment of tasks involving agricultural and animal products which are destined for sale to members, as well as to the implementation of government resolutions that members be supplied in keeping with production plan fulfillment. Here are a few facts. The districts of

Tirana, Kukes and Kruja last year produced the following percentages of vegetables, potatoes and milk, respectively: 105, 107 and 85 percent, while members of agricultural cooperatives were furnished by these districts 28, 4 and 24 percent, respectively. This shows that among certain leaders of agricultural cooperatives there is a lack of proper appreciation for these matters, neglect, lack of responsibility and a breach of the plan's discipline. The financial and banking organs have not concentrated on this problem as they should, following it cooperative by cooperative to correct and adjust the implementation of the tasks of the plan and those of the 1967 Declaration of the Party Central Committee and Council of Mininsters. The executive committees of people's councils and districts and the Ministry of Agriculture need to handle these problems better.

Failure to obtain the planned revenues from commerce, services and savings affects the growth of money in circulation. It is therefore necessary for the financial and banking organs to follow step by step the fulfillment of the plan's tasks by the various sectors of the economy and to struggle to preserve and improve the proportions specified in the plan. A greater effort can be made especially in the districts of Fier, Kruja, Lushnja, Permet, Puke, etc. Possibilities have existed in these districts to accomplish the plan's tasks for covering the buying power of the population better through the circulation of goods, services and increased savings.

This continues to be a problem in 1980. Buying power exists so, therefore, all possibilities exist for accomplishing the plan. However, the results for the first four months of this year in some respects indicate that things are not going well. At several commercial enterprises and at the agricultural cooperatives, deficits have been created and have led, in several districts, to an increase in the amount of money in circulation over the plan. This indicates that the state organs, the district economic organs and the financial and banking organs have not done a good job in tracking production accomplishments, contract implementation and work organization at the commercial enterprises and agricultural cooperatives.

During this four-month period several districts performed well, followed the accomplishment of production tasks and the implementation of contracts more closely, organized the distribution and redistribution of merchandise in the commercial network better and, as a result, achieved fine results. In April the majority of districts, such as Elbasan, Gramsh, Korce, Kruja, Lezhe, Lushnja, Pogradec, Puke, Tepelena and Tirana, achieved and surpassed the plan for goods circulation by cash, reducing part of the first quarter deficits, while such districts as Vlore, fier, Mirdita, Diber, etc., did not fulfill the goods circulation plan.

Overspending on wages and maintenance of a larger work force than planned and unjustified by production continue to be problems. In 1979 several enterprises in such districts as Tirana, Fier, Elbasan, Tepelena, Kukes, etc., ended up overspending. Regarding the maintenance of a larger work force than planned, improvements were made as a result of the proper understanding and reinforcement of bank control. However, at the end of the

year there were quite a few workers over the plan and 268 of them were not justified by output. This means that the demand to implement the plan must be further strengthened. Any concession in this direction carries dangerous consequences because buying power not covered by production is created.

Enterprises in such districts as Tirana, Durres, Elbasan, Vlore, Lushnje and Mat have had overspending on wages this year as well. Some of them likewise maintained a larger work force than planned which was justified by output. However, these enterprises and especially the executive committees of the district people's councils of Berat, Durres, Korce, Shkoder, Tirana, etc. should pay greater attention to this problem, with the goal that the enterprise accomplish the tasks of the production plan with the planned work force and wage fund.

The problems of monetary circulation constitute significant aspects of the implementation of the party's economic and financial policy. They have a profound political, ideological and economic content. Therefore, treating these problems as such, we will struggle and take measures to increase our influence further for the optimum accomplishment of production plan tasks, this being closely connected with the circulation of goods, to strengthen our socialist economy further.

PRESENT, LONG-RANGE PROSPECTS FOR ELECTRONICS INDUSTRY

Tirana ZERI I POPULLIT in Albanian 5 Jul 80 p 3

[Article by Hasan Mucostepe, technical sciences candidate: "Present and Long-Range Problems of Electronics Development"]

[Text] Electronics in our country has achieved a number of successes under the party's continuous attention. Two years following the full electrification of the country on 23 October 1973, the extension of telephone service to all villages was completed. The majority of communications lines has been switched over from wooden to concrete poles and quite a few of them are crowded with high-frequency equipment. In addition to landlines and cables, communications has been established via radio, radio relay and Telex. A complete communications system has been established in the highway, railroad, sea and air transportation networks. The railroad communications lines alone are longer than all the lines which the entire country had in 1950.

Radio and television broadcasting have undergone tremendous development. Radiated power has increased several million times over and a very large number of transmitting stations exists. Suffice it to mention that the electrical energy required to supply radiostations today is greater than all electricity produced in our country in 1950.

Along with communications and radio and television broadcasting, electronics has found application in almost all branches of our economy. The establishment of production sectors for spare parts and electronic devices played an important role in its development. Thus, the radio and television plants, the post and telegraph plant and the communications and electromedical plants built after the 1960's, which grew and expanded very quickly, increased the quantity and improved the quality of their products and have now become a powerful base for the rapid development of electronics.

The electronics industry, although young, has successfully accomplished its assigned tasks, producing communications spare parts and equipment, widely used electronic appliances and various electronic devices for industry and health. The radio and television plant, from the simple

assembly of radios, television sets, amplifiers, recorders, stabilizers, etc., has proceeded to the production of many components, thus reducing the range of imported elements. The post and telegraph plant currently produces about 60 percent of the spare parts requirements for communications equipment and is working to produce 95 percent of these parts in the future. The communications and electromedical plants in Tirana have also achieved successes.

However, despite the accomplishments in this field, problems still exist which demand solutions. The party has requested that electronics be extended more widely and inserted more deeply into quite a few branches of the economy because automation and the application of electronics to production processes leads to an easing of manual labor, reduction in the consumption of raw and secondary materials, growth in productivity and conservation of electrical energy. Therefore, as Comrade Enver Hoxha stressed at the Eighth Plenum of the Albanian Workers' Party Central Committee, specialists, innovators and other workers must constantly ask themselves the question: Is what we are doing the best, the most effective and suited to the economic and social needs and capabilities of our country?

To implement this request, the specialists and workers who work in the various fields of study, production and application of electronics, among other things, are faced with several problems in need of solution, such as: determination of the array of electronic devices, instruments, appliances and systems which can be produced domestically; specification of the production line and the way to produce these devices and appliances.

Organized consultations reached the conclusion to give precedence to the domestic production of electronic equipment for industry. The possibilities exist to produce electronic equipment for automatic weighing, siganling, remote control and protection, measurement and regulation of various parameters in industry, equipment for geophysical research, for the diagnosis and treatment of diseases, for the automation of transportation, command of production-line machinery, instruments for product quality control, etc. Possibilities also exist for the further expansion of the production of equipment for radio and multichannel communications, computer technology, electronic consumer appliances such as radios and television sets, antennas, tuners, amplifiers, recorders, etc.

In specifying the line of production of this equipment, we should keep in mind the party's recommendation that the simpler and more widely used equipment should be produced initially, and then gradually the more complex ones.

Success has been achieved in the production of such auxiliary elements as casettes, tapes, printed circuits, various metal and plastic parts, keys, buttons, contacts, etc., but, keeping in mind the possibilities and significance which these elements have in reducing imports, much remains to be done.

Satisfactory results have also been attained in the partial production of passive elements. The production of transformers, throttles and various inductive coils has begun at the radio and television plant, the electromedical plant has experimented with the production of resistors and is continuing with the production of paper condensors, while the post, telegraph and communications plant has produced and experimented with quite a few other elements. Since the passive and auxiliary elements in every electronic unit comprise over 90 percent of all component elements, the complete production of these elements locally requires the devotion of greater attention to it.

Within this framework, it is necessary to strengthen cooperation between plants of an electronic profile and those of a mechanical and electromechanical profile, to increase attention to fine and detailed mechanics, to intensify study, research and experimental work and to form a cross-section within the group of electronics plants.

TheThe method of producing electronic equipment in support of the active element also holds special significance. Two groups of active elements currently exist: vacuum and semiconductor. Included in the first group are electron tubes, while in the second are transistors and integrated circuits. Integrated circuitry marked the beginning of a new evolution in electronics because it moved from the production of specific active elements to the production of complex electronic diagrams which are formed by the uniting of active and passive elements.

Since electron tubes, transistors and integrated circuits have coexisted for a relatively long time, a discussion of their level of usage and, consequently, the manner of producing electronic equipment is a current problem.

Following current trends in electronics development, we think that we should avoid producing and importing electronic equipment with vacuum tubes, with the exception of instances when their use is still essential. This is for several reasons. The production of widely used electron tubes is on the decline and at present many are no longer produced. At the same time, their price has been increasing. Currently there are electron tubes with are priced 2- to 4-times higher than transistors and 1.5- to 2.5-times higher than frequently used integrated circuits. Besides this, the electronic equipment and devices using tubes have greater energy consumption than do similar units built with transistors or integrated circuits.

It is also necessary to discuss ways to produce electronic equipment based on the degree of use of transistors and integrated circuits. The use of schemes based on integrated circuits has a number of advantages: lower cost, smaller dimensions, greater stability on the job, less energy consumption and lower cost for planning, production and maintenance.

All possibilities exist for us to develop electronics at a faster pace. The party encourages and supports the introduction of innovation in production in this field as well, and our specialists and workers have now acquired a rich experience to carry the work further along.

CURRENT, FUTURE USE OF PHOTOGRAMMETRY IN SERVICE OF ECONOMY

Tirana BASHKIMI in Albanian 4 Aug 80 p 1

[Article: "Stereophotogrammetry in the Service of the Economy"]

[Excerpts] Two readers from Vlore district have asked us what stereophotogrammetry is and how this method helps to solve a number of complicated problems in various sciences. Engineer Agim Kaba from the geology and geodesy enterprise in Tirana gave the editor of our newspaper, Pali Koxhioni, a reply to these questions.

Before the liberation of our country, there was no talk about the science of photogrammetry and geodesy. After the liberation, with the concern of the party, the science of photogrammetry and geodesy, just like all other branches, was raised to higher levels and it confronted and resolved problems which were very important for the economy and for the defense of the country.

Land stereophotogrammetry was used for the first time in our country in the geology and geodesy enterprise in 1974. With the aid of land stereophotogrammetry, topographic maps of various scales (1:500 to 1:25,000) were drawn up. This method has high accuracy and is widely used, especially in mountain areas and in difficult and very difficult terrains, and has great economic efficiency compared to other methods.

Prospects for the development of land stereophotogrammetry are great. All the photographic material dealing with the terrain is processed in laboratories equipped with modern apparatus. In addition to the contribution which this method makes to the study and design of hydroelectric power plants, railroads and other construction projects and geological projects, it opens broad prospects for use in other areas.

In 1976, experiments were made on the use of this method in studies on the protection of cultural monuments. The results were satisfactory. Work should be continued and further expanded in this sector. From 1978 to the present, experiments have been going on in regard to the use of this method for the accurate measurement and detection of defects in various engineering constructions.

Land stereophotogrammetry is a rather new branch of our science and, therefore, our cadres have the obligation to promote it in the service of our socialist economy and of the defense of the country.

LER COMMENTS ON QUALITATIVE CHANGES IN PLANNED ECONOMY

Prague FINANCE A UVER in Czech No 6, 1980 pp 361-369

[Article by Engr Leopold Ler, CSc, CSSR Minister of Finance and chairman of the Government Committee on Planned Management of the National Economy]

[Text] The second half of the 1970's marked the beginning of a new phase of our national economy. We discovered new phenomena and factors greatly affecting the conditions of economic growth which qualitatively differ from previous conditions. We are also dealing with the entire complex of changes affecting the entire international economy from which we are not and cannot remain isolated. I have in mind not only the ever increasing prices of raw materials, fuel and energy as well as other items of our exports, but also the overall changes in the system of the international division of labor, the development of the integration processes, the key position of scientific and technical progress, etc.

The new economic situation requires a change in the existing approach to the problems of our development and an immediate transition to utilizing intensive factors of growth. The new economic situation requires that we carry out the strategic economic policy of our party. Keeping in mind the results of the Fifth Five-Year Plan and the tasks of the Sixth Five-Year Plan, our economic situation was described in the main report delivered at the 15th CPCZ Congress by Comrade Husak, secretary general of the Central Committee, in the following words: "With the Sixth Five-Year Plan, we are entering a new phase in which our economy will develop under more demanding internal and external economic conditions. The extensive sources of growth have for all practical purposes been used up and the increased tasks must be met with the same number—and in certain instances even with a lower number—of workers and with a slower increase in the use of energy and raw materials. The order of the day is to produce effectively and work well. This is the main prerequisite for the fulfillment of the Sixth Five-Year Plan and the growth in the standard of living."

Securing economic development during the present stage of building a developed socialist society will be the result of our ability to formulate our system of planned management ex ante, i. e., to foresee the requirements

of the future and not to be satisfied with the use of those features that stem from the need to solve the already existing situation. Our effort is closely linked to the basic content of the party's strategic line, to the effort to achieve the highest effectiveness and quality of social labor, and to our ability to strengthen the role of intensive factors in the growth of our national economy.

In respect to the questions related to the differences between intensive and extensive factors, there can exist different theoretical and practical approaches. However, as far as the overall approach to the problem of economic growth is concerned, we can see total agreement concerning the differentiation between the quantitative and qualitative method of expanded production. The differentiation between the two basic sources of economic development can be found in Karl Marx: "Production appears at shorter or longer intervals. If we look at the problem from a social point of view, we see production in an expanded scope. If the area of production is enlarged we speak about expanded extensive production; when more effective use of production means are used, we speak about expanded intensive production." We can also find in Marx the determination of the basic factor of intensive growth: scientific and technical progress. Science and technology gave functioning capital the ability to grow independently of capital's impact. It is the scientific and technical progress introduced in production which is a prerequisite and indispensable condition for the extensive growth of the economy. Marx even theroretically anticipated that in the process of expanded production (at his time based primarily on extensive and quantitative growth) there would be a reversal when further economic development became independent of capital accumulation and was primarily based on scientific and technical progress and other sources of intensive growth. Economic theory concludes that growth in its inception is primarily the result of the operation of extensive factors and only afterward do extensive and intensive factors become interrelated while intensive factors become more and more important.

The economic policy of the CPCZ since 1945 has been based on these basic scientific notions of the Marxist-Leninist economy. And the CPCZ has been applying these notions in practice. This scientific thesis was translated by K. Gottwald into an absolutely clear directive of economic policy in the determination of the basic principles of socialist construction in the CSR: K. Gottwald emphasized that we had to fulfill the First Five-Year Plan in all branches of our economy not only quantitatively but also qualitatively, that it was necessary to discover and mobilize hidden resources of our economy in order for our nationalized industry to produce more, better and cheaper than had been the case under the capitalist system. This thrust of our economic policy has lost none of its validity, rather the contrary.

Our party gradually analyzed the economic results achieved and the direction of our future steps. A significant role was played by the February 1957 plenum of the CPCZ Central Committee which for the first time openly

tackled the question of effectiveness. Even under a favorable dynamic development of the national economy, we encountered disruptions in certain basic economic proportions which functioned as a barrier against the influence of intensive factors. Material costs, labor productivity and its relationship to wages, etc., developed in a very favorable way. We encountered strong tension between resources and needs. The above-mentioned plenum of the CPCZ Central Committee decided on the following tasks: to overcome the difficulties by adopting complex measures in all branches of production and in planned management, to secure in a planned way the growth and structure of industrial production with special emphasis on the accelerated development of the fuel, energy, metallurgical and chemical base, to strengthen the role of long-range planning, to evaluate the effectiveness of the creation of large economic units operating on the basis of enterprise khozraschot, and to use value categories in the management of the national economy.

The breakdown of these ideas into specifics was done correctly. The Third Five-Year Plan was, however, incorrect in its overall structure. Added to this difficulty were certain external circumstances affecting the economic development of our country. Hence, it was necessary to manage our national economy by completely different means in order to quickly deal with the economic problems we faced.

After mastering this task, the Czechoslovak Community Party once again dealt with the question of economic management at the plenum in January 1965. This resulted in the adoption of directives whose aim was to improve the system of planned management. However, these directives were spelled out at a time when rightwing forces were in the ascendancy and when correct ideas were misused.

For this reason, the May plenum in 1969 charged in the Realization Directive the new party leadership with the task of repairing the disrupted system of planned management and to bring the economic policy of our party back to Leninist principles. The resolutions of the 14th and 15th CPCZ congresses set the directions for further policy. On their bases we achieved, during the 1970's, good results and realized the basic goal of the strategic line of socioeconomic development and building of the material-technical base of a socialist society, i. e., the securing of dynamic development of the national economy and strengthening and developing the standard of living. Between 1971 and 1975, the national income grew at an annual rate of 5.6 percent and social productivity of labor, 4.6 percent. Between 1976 and 1979 we further strengthened, under relatively slower rates of growth of our national economic aggregates, an economic potential and continued in our economic development: the average annual growth of the national income was approximately 3.8 percent.

Certain structural changes showed positive impact in the first 4 years of the Sixth Five-Year Plan: we have further strengthened the role of the engineering and chemical industries and of those productions which depend

on domestic raw materials, and we have paid greater attention to long-range developmental programs in these areas. The integration of our national economic complex in the international division of labor has improved; this applies primarily to the process of socialist economic integration. We are succeeding in realizing the resolutions of the 15th CPCZ Congress in the areas of material and cultural level of our citizens.

The positive results so far achieved must be really appreciated because they were materialized under demanding economic conditions. The communist party, however, not only analyzes the development of the national economy from the point of view of positive aspects--which are undoubtedly here--but also systematically examines the factors of economic growth. The overall economic development of the Sixth Five-Year Plan, especially the creation of material resources, is slowing down and the securing of this development is accompanied by tension within certain important sectors of our economy. A report submitted by the presidium of the CPCZ Central Committee to the 14th plenum stated: "The basic cause for a lower national income is the insufficient level of the overall effectiveness of the production process..our economic activity in both the area of the formation of the national economic plan and in its realization has not been able to adjust itself to new and more demanding conditions."

Czechoslovakia's position in the international division of labor and the development of external economic conditions, which experienced a basic change during the 1970's, significantly affect the economic development of our country. When the world energy crisis started, we spent annually 4.5 percent of our hard currency to purchase crude oil and natural gas. However, in 1980 this item represents 15 percent of our balance of payment and we estimate that this will increase to 25 percent during the next Five-Year Plan. We have not yet been able to deal with the problem of changes between export and import prices. Thus while during the Fifth Five-Year Plan we could use the entire gain realized from the final product for meeting domestic needs--and half of that for the growth of consumption--during the Sixth Five-Year Plan we must set aside 30 to 40 percent of this gain to meet the accelerated rise in import prices; and now the figure is already 50 percent.

The possibilities of further economic growth of the CSSR now only rest in a consistent utilization of intensive factors and the application of such means as the development of scientific and technical revolution, the introduction of modern methods of management, and stronger participation in international socialist integration. Especially, the full utilization of the possibilities of scientific-technical progress and its accelerated and broad application in production is the only possible alternative for further development of our socialist economy.

On the basis of a decision made by the party leadership, a complex experiment in the management of effectiveness and quality, which has already

been carried out in 17 VHJ's, was introduced on 1 January 1978. At the same time, work started on a uniform system of measures which would qualitatively move the system of planned management into a new direction in order to better meet the demanding economic conditions of the 1980's.

It is necessary to consider that during the 1980's, we will achieve lower rates of growth than was the case in the past. At the same time, we must greatly improve the level of utilization of energy, raw materials and other materials. It will be necessary to reevaluate a number of values and their priorities in order to secure the functioning of our economy. In this connection, there could appear voices of economic pessimism or ideas of so-called zero growth. However, it is not the shortage of energy, raw materials or manpower which act as a barrier to our economic development. Rather, the barrier is insufficient effectiveness in the evaluation of these factors. The overcoming of this obstacle is a prerequisite for a guarantee of the successful and steady economic growth of our country.

It is necessary to change economic thinking in order to replace the existing parameters and criteria, which played a positive role for the past 30 years, by more demanding ones. We must create an economic climate which will permit all economic levels of management, which will decide on and approve future measures, exposing them to real pressure, forcing them to greatly improve effectiveness.

The new system of measures aimed at improving planned management in the period after 1980, adopted by the presidium of the CPCZ Central Committee and the CSSR Government, is a long-term document whose provisions will be carried out during the next Five-Year Plan and possibly during the one that will follow. It consists of a series of measures deeply affecting the existing management system which will gradually be introduced on the basis of new situations. Viewed from this angle, it is necessary to emphasize that the adopted system of measures is not a "closed" one, but that it is an appeal addressed to all involved members of our society possessing knowledge and experience to step forward with new ideas.

The uniform planned management of the national economy includes planning the national economy in the form of creating or directing the national economic proportions ex ante, management of economic subjects from a center and, last but not least, organization of the production structure of the national economy.

The plan of development of the national economy occupies a key position in the economic mechanism of a socialist society. The increased demands put on the plan and the entire economic mechanism are related to the growth of volume of production, the complexity and interdependence of economic relations and the progress of the scientific and technical revolution. All management and planning work must, under existing conditions, aim more and more at increased production efficiency and quality, at higher final national economic results and at better satisfaction of growing social and personal needs.

At the same time, it is primarily up to the plan to orient our system toward rational utilization of the resources of the national economy, utilization of intensive factors of growth and broad application of scientific and technical ideas in production. In this respect, the plan's improved quality and its growing role in the economic mechanism are increasing. Another result is the strengthening of the plan's long-term prospects, proper balancing procedure and a well-thought out approach during the plan's drafting stage, and the strengthening of the plan's norm-setting base.

The adopted system of measures, while permitting a uniform system of plans, is based on the fact that the plan functions as the main instrument for realizing the economic and social policy of the CPCZ. All measures toward improving the plan aim at more effective use of intensive growth factors by effecting the most important qualitative and structural factors of changes based on applying the results of scientific and technical development. The main task in regard to the development of the national economy--structural changes, participation in the international division of labor, scientific and technical development--can be evaluated and realized only in the long run and in a planned way.

The new system eliminates the shortsighted approach to planning and management and the existing practice of determining tasks with the help of intra-annual indices of development of individual indicators on the basis of results of the previous economic year. The five-year plan becomes a really basic form of planning and a basis for organizing economic activity at all management levels. Within the framework of the five-year plan are determined the main tasks, limits and economic conditions for specific years which must be consistently assigned to the appropriate levels of management, namely, to the VHJ's or enterprises.

At the present stage we are working on the final state programs which incorporate the basic structural changes of the economy and which will be oriented toward the most important tasks of scientific and technical development and toward measures and actions for integration within the CEMA.

The main role of annual plans is to secure the goals and tasks of the five-year plan. The point of departure for the drafting of the plans will be the tasks, limits, instruments of the material incentive and other economic conditions determined by the five-year plan.

Annual plans must react operationally to changing domestic and external conditions, to new phenomena and needs during the course of the five-year plan. Also, the method of control and evaluation of the plan is being changed. We are primarily interested in fulfilling the five-year plan right from its inception and in control and evaluation of the fulfillment of individual annual plans. The primary criterion of control and evaluation will be fulfillment of the specified tasks, especially in regard to the growth of effectiveness, quality and export efficiency and in regard to achieving results from the scientific and technical revolution.

In a certain sense, it is a fact that the five-year plan is decided upon at the top, at a center, and that the annual plans are put together by lower-level organizations. In order to strengthen this trend, we must increase the interdependence of tasks and instruments of material incentive in such a way as to make advantageous the adoption of more challenging tasks, especially those relating to higher quality, in the annual plan and punish failure to meet these tasks. On the interdependence of tasks and the material incentive will depend the stimulation of operational plans which are seen as a decisive form for the participation of the working people in the drafting of the plan. In connection with these measures, directives concerning the drafting of annual plans in the old form are being discarded.

The improvement of the plan depends on improved planning, management and organization of the material relations in the national economy. This is, for all practical purposes, the basic prerequisite for improving internal relations and for the harmony of the plan. In order to achieve that, we have adopted measures aimed at creating a finished system of material and price balance sheets, in the first place of structural and marketing balances, and improving the system of balances at all levels of management. Some measures also have as their goal the strengthening of supplier-customer relations during the drafting and realization of the plan and the stipulation of these relations in written contracts.

The number of material balance sheets for the Seventh Five-Year Plan is being increased in the state plan to 343. At the level of intermediate organs, the balance sheets will have 120 items and at the level of the VHJ's, 230 items. The highest number of balance sheets will be in the engineering industry where we even anticipate balance sheets for complete plant equipment, including important complete products. In all, the balance sheets to be used in the state plan will be used for more than half of industrial production.

The plan will be clearly oriented toward the qualitative aspects of the reproduction process. The system of indicators also expresses the tasks in increased effectiveness, technical level and quality of products and meeting the needs of customers. The fulfillment of the plan and achieved results can no longer be evaluated merely on the basis of gross production. To regulate the basic wage and to calculate labor productivity, we will use an indicator of net production, namely, actual output. The fact that this indicator does not include material costs is in line with today's needs for maximum savings in the use of raw materials and materials, higher effectiveness of production funds, etc. Savings on materials will be significantly reflected in the fulfillment of the indicator of output (via profit growth). For example, in industry 1 percent saved on material will result in a 3-percent increase in output. In a similar way, we also will see increased value of technically progressive products and products listed in the first quality group.

Another indicator aimed at the qualitative aspect of production, namely, the returnability on funds spent on machinery, equipment, reserves and buildings, is the rentability of production funds. This means that individual economic units must make sure that the growth in labor productivity will be accompanied by the reduction in materials and funds needed for production.

The system of measures also makes more precise qualitative parameters for the realization of tasks in research and development, price limits of new products, growth of per kilogram prices of imported products, etc. The establishment of the indices of effectiveness, such as labor productivity, cost development, the use of basic means, etc., must be preceded by a thorough analysis of factors influencing development. At the same time, it is necessary to keep in mind that this is not a case of exchanging one indicator for another but a change in the approach toward decisionmaking, a change in economic thinking where effectiveness and quality must be the point of departure.

Khozraschot relations are a demonstration of a relative economic independence of enterprises or VHJ's, stemming from the achieved level of production forces reflected in a given stage of development of social division of labor.

Khozraschot is a basic method of economic management securing planned incorporation of production units into the entire complex of the national economy and creating prerequisites for multifaceted development of initiative and relative economic independence of these units. It is a well-rounded system of economic relations between society and economic subjects and among the latter, based on planned utilization of commodity-money relations with the goal of stimulating economic effectiveness of production in accordance with the tasks set in the national economic plan. Recently, in most of the CEMA member countries the system of khozraschot relations is being extended and improved in connection with the improved system of planned management and the transition toward the utilization of intensive growth factors.

The system of measures includes principles, regulations and instruments aimed at increased effectiveness of khozraschot as a whole and its individual elements in order to ensure the growth of effectiveness and quality. Responsibility of individual VHJ's and enterprises for economic results is being increased. Favorable and unfavorable results of activity will more than before affect their evaluation, material incentive and financial economy.

Other economic methods of planned management, namely, credit and financial policy, pricing mechanism, and the wage system will work in a similar way.

The basis for improved effectiveness of khozraschot is long-range planning where the basic scope and instruments for the functioning of khozraschot

are determined within the framework of a five-year plan. This will be manifested in increased dependence of personal and collective incentive not only on results achieved in the production sphere, but also in relation to results in the sphere of investments and reproduction of basic funds as well as in the spheres of supplies and financial resources.

The share of financial resources of the VHJ's, especially of profit, in financing the VHJ's needs and in the formation of incentive funds, is being increased. In order to secure a change in financing investments (subsidies from the state budget for investments will be used only in exceptional cases), the share of profit used for this purpose in the khozraschot sphere will be increased. While during the Sixth Five-Year Plan the profit, after the payments in the khozraschot sphere, was approximately 20 percent, we anticipate to gradually increase this share to 30 percent and in the long run to 40 percent.

The effectiveness of the formation and utilization of incentive funds is being greatly increased. These funds will be created on the basis of norms and their formation will depend on the fulfillment of specific indices and on the formation of usable profit. These funds will be greatly affected by nonfulfillment of the planned profit or by deductions from profit as a result of fines, penalties for inferior production, etc.

Certain incentive funds will, in comparison with the existing situation, be reapplied (the development fund); in the case of others, their influence on the incentive (export-stimulating fund and fund for cultural and social needs) will be increased.

Material incentive in the growth of effective imports, especially from the point of view of prices paid on foreign markets, will be strengthened in regard to the significance of external economic relations.

The tasks of the foreign trade plan and the criteria of its effectiveness will play a decisive role in the selection and orientation of complex developmental programs, in the allocation of investments, in the directions of production and in the management of technical development and quality. The system of measures enlarges the scope of relations of the five-year plan and the operation of financial and economic instruments for material incentive in adopting and fulfilling progressive export tasks. We anticipate the realization of the tasks of the five-year plan in the export sphere with the help of annual plans, especially in accordance with the development of foreign prices.

We will also gradually create prerequisites in foreign-exchange rates and in the management of wholesale prices in order to establish higher criteria for an effective relationship between khozraschot and the international division of labor, especially as far as the process of international socialist economic integration and for a realistic view of the situation at foreign markets are concerned. Gradually, we will spell out a price

mechanism in such a way as to set the prices of raw materials, fuel, materials and imported machinery and equipment in accordance with the development of the purchasing cost, i. e., import prices.

The application of the principles of closer dependence on the effectiveness and quality in the activity of khozraschot units will bring forward differences in the formation of resources among individual VHJ's and enterprises. There will be a difference between well-managed and badly managed enterprises and the intensity of economic pressure on the effectiveness of production will increase.

The development of khozraschot at the level of VHJ's is linked to its improvement at the level of enterprises and to the improvement of the intraenterprise khozraschot. We will work out rules for improved management within the VHJ's and the development of effective forms of intraenterprise management. Centrally determined principles for the development of khozraschot will serve as a basis for the solution of the above questions.

The tasks of the present stage require that the social division of labor in the management sphere be adjusted to the new economic conditions. These tasks require a new division in regard to jurisdiction and responsibility in the management of social production. The most important characteristic of this process, related to the ever increasing level of social production, is the transformation of the VHJ's into basic units of management in the khozraschot sphere and the increase in the standard of central national economic management.

The system of measures includes tasks for improving the most important areas of the management system assigned to organs of the state administration and economic organs. The mastering of the demanding economic tasks during the next period anticipates great improvement in the work of central managing organs of individual sectors and branches. The improvement in the work of central management must be demonstrated especially in its conceptual, coordinating and controlling roles, and in broadened responsibility for the solution of decisive national economic tasks, scientific-technical development and structural changes, and for the superior drafting and realization of national economic plans.

The transformation of the VHJ's into basic units of management is based on the resolutions of the 15th CPCZ Congress. The VHJ's will be given all necessary means, jurisdiction and responsibility. To this also are related changes in the organization of the production-technical base aimed at the creation of uniform production economic units able to secure the conceptual development of production and of individual branches, the drafting and realization of a uniform technical and investment policy, the needs of the national economy, and the development of external economic relations.

The enterprise still remains an important element of management in the newly outlined jurisdiction of the VHJ's. It is fully responsible for

effective and quality production based on the needs of customers and for multifaceted care and social development of the working peoples' collectives.

However, improving the plan, khozraschot, and organizational structure of the economy will not by itself secure the achievement of specific tasks. The process of improving the entire economic mechanism sharply increases the demands on management workers. To understand the meaning and tasks of the economic policy, to adopt a genuine party approach toward the realization of approved measures, to show high organizational ability and tenacious effort to achieve the stated goals, to be able to offer leadership to workers and work with them, to develop their initiative, to fight for everything new and progressive--these are the demands which we are asking today from all managers.

The most decisive element for successful realization of the system of measures will be the way in which the subjective factor, namely, the people and especially managers, identify themselves with the scope and goal of the system and in which they carry out the necessary measures in practice. The success of the party's economic policy depends primarily on the cadres, namely, on their preparedness, responsibility and achievements.

The complexity of the economic development and progress of our society requires higher demands on the political and technical maturity and moral quality of managers, their ability to manage workers, creatively develop and consistently carry out the policy of the party within their jurisdiction. Leading workers must be subject to regular and rigorous evaluation which takes into consideration the results achieved and good care must be taken for their development.

To achieve the full application of the improved system of planned management requires the utilization of all existing resources, improvement of our participation in international socialist economic integration, the solution of new problems stemming from changes affecting the world economy, and the ability to better apply the results of science and technology as the decisive factor of the growth of labor productivity. As stated in the report submitted by the presidium of the CPCZ Central Committee at the 15th plenum of the Central Committee: "Those managers at any level of management who do not understand that will not be able to master the assigned tasks. The improved system of management and planning of the national economy puts qualitatively higher demands on education, people's consciousness, on the level of management and requires the maximum creative efforts of all workers' collectives."

At the same time, it is also necessary to pay systematic attention to sufficient room for the initiative and creative approach of the working people in order that their activity not be stifled by red tape and shortcomings in the organization of labor and management. The participation of the working people in management is a means for cementing the working

collectives, it is a vehicle for unifying individual, collective and social interests, and especially it is a means for relating the communist party to the everyday activity of workers, technicians and managers.

The present level of management, including certain elements of the existing system of management planning, is outdated and does not correspond to the changed circumstances and possibilities of our national economy. I have in mind especially those elements of management who orient production to the utilization of extensive favtors and who more and more have problems with increased effectiveness. Similarly, the level of managing work in many sectors runs counter to the needs of present and future development.

The communist party and the top state economic organs react to the changing situation: the recently adopted system of measures for improving the planned management of the national economy in the period following 1980 insists on changes in the planned management which singularly aim to support the qualitative aspect of the reproduction process.

The effectivaness of the adopted measures depends on the way in which these steps are consistently specified and applied at all levels of management in the processes of decisionmaking, control and evaluation of results of the activity of organizations, collectives and individuals. This was also emphasized by Comrade Husak, secretary general of the CPCZ Central Committee: "The most important task we are facing now is to breakdown the adopted system into specifics. All organs must approach the implementation of the new system together and responsibly. They must give maximum care to the preparation for the gradual introduction of the new system in practice in order to make it a really effective instrument for the solution of the tasks of our national economy."

AGRICULTURAL MECHANIZATION TRENDS FOR SEVENTH FIVE-YEAR PLAN

Prague TECHNICKY TYDENIK in Czech 15 Jul 80 p 6

[Article by Frantisek Kral: "Agriculture in the Seventh Five-Year Plan"]

> [Text] Preparatory work for the Seventh Five-Year Plan is climaxing at this time in all the national economic branches. This is also true in agriculture which faces demanding tasks of implementing the resolution of the Thirteenth Session of the CPCZ Central Committee. The principal goal in the coming period will be increasing self-sufficiency in food production. Suffice it to recall that, for example, the production of grain in the Seventh Five-Year Plan is to reach 56 to 58 million tons which, compared with the expected results in the Sixth Five-Year Plan, represents an increase of 3 to 5 million tons. The annual consumption of dairy products is to rise by the end of the next five-year plan to 250 kilograms, and the consumption of meat to at least 90 kilograms per person. Consumption of vegetables by 1985 is to grow to 91 kilograms, and fruit to 65 kilograms per person.

In this coming phase which is characterized by a substantial increase in agricultural production, along with a further decrease in the agricultural labor force, implementation of all these plans depends on an overall increase in labor productivity which will require a corresponding advance in agricultural technology.

Therefore, we must reach a qualitatively higher plateau in the technological base which will be expressed primarily by a substantially higher performance rate of individual machines, operating equipment, and machine systems, by higher installation performance of the energy base and changes in its structure, and by completing comprehensive mechanization in all basic production branches, along with transition to mechanization in especially the stationary production processes. In order to better utilize technology, we plan to expand the services for specialized activity (agronomical enterprises for fertilization processes, etc.)

The required trends of agricultural technological development of the period after 1980 are defined in the Czechoslovak System for Comprehensive Agricultural Mechanization which was prepared on the basis of results of technological research, testing of modern foreign technology, and the experiences of a broad collective of workers in the agricultural and engineering branches, both theoreticians and practitioners. According to this system, the coming period will be marked, with respect to automotive technological equipment, by an expansion of automobile transport techniques, in addition to increasingly broader use of self-operating machinery.

We plan to set up a unified, mutually-complementary system of automotive equipment, that is, unified basic centers in one category (motor, transmission, drive and steering systems, hydraulic and electrical outfitting, control and cabin) with which it will be possible to complement, together with the work force, mechanized equipment of various types (tractors, self-propelled machinery, trucks). This will enhance the serial nature of production, reduce operational expenditures, and service and maintenance costs in agriculture.

The anticipated development of installed performance of individual types of mechanized equipment, stemming from the reality of 1975 and the delivery plan through 1980, is shown in the following table.

Indicator/Year	1975	1980	1985
Tractors	5.35	7.4	8.2
Trucks	2.26	3.6	5.5
Automotive Machinery	1.77	3.2	4.7
Performance of Mobile Power Euipment Overall (10^6 kW)	9.39	14.2	18.4

A serious problem in the coming period will be agricultural transport and handling of materials. At the present time, transport, loading, unloading, represent 40 to 45 percent of the overall mechanized effort per unit of production, and about the same percentage of human labor needs. Tractor transport is dominant in agriculture, handling about 70 percent of the overall volume of transport. Utilization of tractors, however, no longer satisfies the standards for effective transport operations required under conditions of advanced socialist agricultural mass production.

The volume of agricultural transport represents roughly one quarter of the overall volume of road transport. Yet the share of agriculture in the number of conveyer vehicles in the national economy as a whole is only 12.2 percent, and less than 10 percent of the overall tonnage. Consequently, we

have to make sure, in accordance with the resolution of the Thirteenth Session of the CPCZ Central Committee, that in the Seventh Five-Year Plan the agricultural sector will receive 10,000 specially adapted agricultural freight vehicles with a capacity of over 8 tons, including special equipment attachments, trailers, and 6,500 loaders reflecting agricultural needs.

With respect to vehicles required by the system of mechanization, we anticipate a transition from tractor to automobile techniques with the following parameters:

--capacity of 10 to 12 tons in trucks with a system of tecnological attachments (fertilizer spreaders, industrial fertilizers, liquid manure, lime, dross, etc.);

--capacity of 16 to 20 tons in trailer systems with a set of technologically-specialized equipment (collapsible panels, flatbed conveyer, cisterns, cattle conveyers, etc.);

--utilization of autotractor container systems for combining tractor and automobile techniques in basic 10-ton capacity, with special-purpose containers usable as transport crating, temporary storage, or technological equipment;

--self-propelled transport technology (automotive harvester vehicles of 4-to 7-ton capacity, automotive application technology, special vehicles for mountainous regions).

Exploitation of highly-productive transport equipment would be impossible without simultaneous introduction of a broad series of standard loaders, especially of the self-propelled type.

In transport of fertilizers to the fields and in spreading, we anticipate a gradual transition to a proportionate process based on supplying the ground spreaders with self-emptying conveyers. There will be further application of spraying from the air, especially as a result of proportionate nitrogen content applied during the growing period. In the application of liquid fertilizers we will, for the sake of plant protection, gradually introduce self-propelled machinery with an effective range of 20 meters, instead of the universal tractor sprayers.

Future outlook in soil processing requires that technological development take the road of high-performance mechanized equipment, including wide-angled plows with a capacity of as much as 3 ha. h^{-1}, broad application of new agronomic discoveries (lowering the depth of plowing, replacing plowing with underplanting with disc underplanters or chisel-type soil cultivators, introduction of seeding in unprocessed soil) and utilization of combines. In order to reduce breakdowns of not only soil processing machinery, but especially harvester equipment, we must employ rock-picking machines in rock-filled arable areas.

Grain will be harvested in the coming period by harvest threshers of 8 to 10 $kg.s^{-1}$ penetration, instead of equipment used presently with a penetration capacity of only 4 to 6 $kg.s^{-1}$. For harvesting on slopes we will use equipment with a capacity of 5 $kg.s^{-1}$ penetration, instead of standard threshers.

In the harvesting of fodder, which will continue to be a subject of special attention, we will stabilize two basic methods, namely, harvesting with self-propelled cutters and harvesting with pick-up vehicles. Harvesting cutters with appropriate adapters for both mowing and pick-up of thin-stemmed fodder and silage corn, will become a significant factor in universal application, including on slopes up to 10 to 12 degrees. Along with these machines, we will use pickup vehicles, the need for which is especially vital due to the size of slope areas (over 500,00 hectares), and we do not exclude their use even in flat areas (fodder vehicles, stacking of hay, etc.).

Much attention will also be devoted to mechanization in growing and harvesting potatoes, which remains at an unsatisfactory level. In harvesting late potatoes, we will gradually introduce three-row trailer harvesters and, in the near future, four-row automobile harvesters with 0.6 $ha.h^{-1}$ capacity, which will be servied by four workers. Also needed are special adapters for harvesters of consumer potatoes and the cultivation of crops, as well as on slopes up to 8 degrees.

In sugar beet harvesting, the two-phase technology will be fully applied, even though it is not inconceivable that the phases will be split differently for partial drying of the beet-tops in the rows.

Further technological steps will include lowering of the trend toward wastefulness in the present wide variety of machinery. Seeding and cultivation machines will be replaced by a 12-row self-propelled machine which will handle the following operations: sowing and application of herbicides and pesticides, rotary hoeing and plow-blade hoeing, and automatic sorting.

Mechanization of growing and harvesting vegetables and fruit is still at a low level. We envisage a substantial improvement in the coming period, we have high expectations regarding new types of machinery which will be developed and produced by the international enterprise AGROMAS.

Mechanization of labor in the animal production industry will be handled in accordance with the construction of new installations and extensive modernization of existing ones. Further development will be governed primarily by the requirement of achieving a point of minimum manual labor, maximum quality products, and a high level of hygienic safeguards.

In cattle breeding we expect a more intensive transition to vertical storage areas and stationary feed-lines equipped with elements of self-operated regulation and automation. In the future, we can expect computerized control.

Increasingly, we encounter efforts toward more effective utilization of all types of fodder by means of homogenization, processing, and optimum fodder composition. With gradual concentration, we use centralized fodder preparation and mixing installations, especially for bulk fodder.

In milking equipment, technological development focuses on automation of individual work phases and, in the future, we envisage installation of an automated milking process with the use of computer technology.

In hog breeding, we plan stationary mechanized feed lines, programmed automated operations, and minimum requirement for servicing. There will be significant growth in the use of multisectional stalls in one-level or multiple-floor construction.

In poultry breeding, we are leaning exclusively toward pen technology which will continue to be improved and applied in multisectional construction. We envisage that, starting with 1985, this method will be fully operational in the production of eggs and fowl breeding, and especially in poultry production.

In sheep breeding, which will be expanded, we plan gradual mechanization of labor, including milking. In this area also we can expect application of the multisectional stalls method in lamb feeding.

The implementation of the above-mentioned principal trends of techological development in agriculture, designed to meet the tasks of the Seventh Five-Year Plan, will increasingly depend on how other branches meet their material and technological needs, and with what degree of effectiveness agriculture is able to put these means to productive use.

CSR MINISTER CALLS FOR LOWER GRAIN LOSSES DURING HARVEST

Prague HOSPODARSKE NOVINY in Czech 15 Jul 80 pp 1, 6

[Article by Miroslav Petrik, CSR minister of agriculture and food]

[Text] Production of grain is becoming increasingly important and represents the basic prerequisite for successful future development of socialist agriculture. Harvest activities which climax the year-long effort in this sector are therefore a highly significant task, the preparation and successful fulfillment of which must be given constant attention at all levels of agricultural management, as well as by interested ministry organizations which contribute to a smooth accomplishment of this task.

The results of this year's harvest will have a decisive impact on the fulfillment of the Sixth Five-Year Plan in grain production, and on the creation of a launching platform for the development of agricultural production in the Seventh Five-Year Plan. Consequently, in accordance with the resolutions of the Thirteenth and Fourteenth Sessions of the CPCZ Central Committee and with the goals set forth by the Fifteenth CPCZ Congress, we approach this year's harvest with a high degree of exactingness in further increasing self-sufficiency in the production of those foodstuffs which can be grown in our temperate climate.

Edible Plant Development

The state plan decrees that the CSR will produce this year 7.150 million tons of grain, i.e., 11.1 percent more than the annual average in the 4 years of the Sixth Five-Year Plan. Expressed in fiscal terms, such production volume represents more than 50 percent of gross plant production on arable land. Purchases of legumes for the state inventory are to amount to 110,000 tons, i.e., 3,000 tons more than the plan for 1979. In winter rape, where seeding areas were expanded last year, market production has risen to 130,000 tons, which is 10,400 more than the plan for 1979.

Based on detailed evaluation of the results and causes of varying hectare yield in grain production in past years, ever since the completion of last year's harvest the whole system of agronomical measures has been oriented not only toward fulfillment of high production volume, but primarily toward good quality winter wheat for bakery needs and spring barley for malt production.

In order to meet the demanding task in grain production, a good launching platform was created in the fall of 1979 when sowing of winter crops was accomplished in most agricultural enterprises without serious problems and within optimum agronomical deadlines. Winter crops in the CSR were seeded on an area of 1,042,464 hectares, of which winter wheat on 765,102 hectares, winter rye on 136,988 hectares, winter barley on 74,844 hectares, and winter rape on 65,530 hectares. Significant movement occurred in the structural composition of winter crops in favor of rye by about 34,000 hectares, and winter rape by 24,000 hectares, as compared with 1979.

There was no serious damage to plants last winter and seeded winter crops survived the season very well. Losses through plowing were minimal (below the average of past years).

Due to rainy and cool weather, seeding of spring crops was delayed by more than 2 weeks, compared with the average of past years.

The prolonged period of cool weather in April and May also had a negative effect on the development of all field crops. Development of grain to date is highly uneven, both with respect to individual types and individual areas.

As a result of this, there is considerable variance in the development of winter and spring crops. The state of winter grain and rape can, on the average, be considered good to very good. The state of spring barley is generally weaker.

Agronomical measures in cultivation are designed to eliminate disease, weeds, and insect damage, and to apply the method of differentiated extra-racine nourishment.

We anticipate that harvest activity will be initiated 10 to 14 days later than in normal years and will be contracted into a shorter time period. Judging by present development, excepting winter rape and barley, harvesting of the principal grain crops will not begin until late July and will extend, in greater measure than in previous years, into September.

Technological Preparation

Consequently, technological and organizational measures will be directed at thorough preparation of people, machines, transportation, and storage, so that the harvesting of winter rape and all types of grain can be executed with high quality and in the shortest possible time period--thus avoiding great operational congestion in September--and so that a smooth passage into autumn activities is ensured. For cereal and winter rape harvesting, we will have this year in the CSR at our disposal a total of 12,529 harvester threshers, of which 7573 E-512 type, 563 E-516s, 3155 SK-5s and SK-6s, and 971 of the older SK-4 type. In preparing for emergency situations, we have established within the VHJ [economic production units] Machine and Tractor Stations [STS] and Agricultural Machinery Repari Shops [OZS], an operational reserve of 300 threshers.

In the interest of economy in propellants, there is more emphasis on intensification and expansion of a cooperative process of harvesting technology involving shorter distances, such as within okreses and krajs. According to contracts concluded to date, an overall number of 8,548 threshers will be included in this project. By applying this system, we can reduce the average load on each harvester thresher from the former 128.6 hectares to 99.7 hectares.

The overall process of preparation and maintenance of harvesting technology is under regular scrutiny in the Czech Ministry of Agriculture and Food by a commission of experts which, with the participation of interested branches, deals with the problem of machinery spare parts. The ministry is in permanent consultation with supplier organizations and foreign trade enterprises on ways to secure adequate spare parts inventory for needed technological repairs. Nevertheless, results in this area are still unsatisfactory. As late as mid-June, a number of items in the spare part inventory for harvester combines were still unavailable. There are shortages especially in flat transmission belts, conveyers, and spare parts for cutting mechanisms. As a result of the fact that the cutting mechanism of the grain combine E-512 is of a similar type as that in imported cutters and presses, shortly before the hay gathering season we encountered an anomalous situation in which the needed parts of the cutting mechanism in already repaired grain combines were dismantled for use in hay gathering operations.

In an effort to at least partially improve this highly negative state of affairs in the spare parts inventory, we have spotted bottleneck items suitable for renovation which is performed in STS and OZS VHJs, as well as in agricultural enterprises and sponsoring plants. In the course of the harvest, we will set up an emergency reserve of selected spare parts. We will also establish emergency services in the STS and OZS VHJs and the sales network of the Central Enterprise for Agricultural Technology, which will service breakdowns and issue spare parts. We have already set up within the Central Enterprise for Agricultural Technology a nationwide communication and delivery system to handle necessary transport of needed spare parts.

Adequate fuels and energy deliveries for this year's harvest operations are ensured for agricultural enterprises and procurement organizations in the state plan. There is a precarious balance in light heating oil this year since, compared with real deliveries for agriculture in 1979, the overall ceiling is down by 44,000 tons. Kraj and okres agricultural administrations, directly managed organizations, and agricultural enterprises must, for the duration of harvest operations carefully manage the oil supply and lay away an operational reserve for use in case of inclement weather. An operational reserve necessary for special conditions during the harvest was set up under the jurisdiction of the ČSR Ministry of Agriculture and Food. With the help of the national committees we are securing adequate deliveries of coal and coke from the Coal Storage Enterprises for dry grain products. Deliveries of city gas and natural gas

will, during the peak period, be handled in cooperation with the communication and delivery system of the Czechoslovak Gas Enterprises.

The aim of all these measures is to ensure full use based on need of drying facilities in the course of the harvest, especially in damp weather.

The Best Grain for State Inventory

State purchases of grain in the CSR for this year are set at 2.280 million tons, i.e., 50,000 more than in 1979. In the interest of guaranteeing the best grain for food processing purposes, procurement tasks were included in the enterprise plans for food-producing oats, the volume of which will be stimulated via prices. Our aim is to purchase the best grain for state inventories.

For storage of grain from this year's harvest, procurement organizations and agricultural enterprises will have at their disposal a storage capacity of 7.014 million tons. In comparison with last year, storage capacity has increased by 148,000 tons. For storage of contracted amounts of grain purchased during the harvest, there is a shortage in storage capacity of 144,000 tons. Consequently, certain branches and kraj national committees were asked to help find space for temporary grain storage. In addition, within the branch, measures are planned in the VHJs of the processing industry to accept a maximum amount of grain already in the course of the principal procurement season, and provide temporary storage facilities in appropriate installations. Furthermore, we are readying a 5 percent storage reserve for use in case of inclement weather.

Much attention is devoted to readiness in cleaning and drying installations which are an important factor in rapid harvest operations and full utili-ation of harvest threshers. Their overall capacity has increased this year to 19,800 tons per hour, i.e., 1,600 tons per hour more than last year.

In order to achieve harmony and coordination of post-harvest operations with regard to smooth grain transit and elimination of losses in storage, additional storage facilities in procurement organizations and agricultural enterprises have been equipped with adequate ventilation systems. By the time of the harvest, enough of these will be available for storage of 2.160 million tons of grain, i.e., 214,200 tons more than last year.

More attention will be given again this year to making sure that the best grain is reserved for food and malt production. In the enterprises of the Agricultural Supply and Procurement complex, we have arranged for separate storage of the highest-quality wheat for bakery purposes and barley for malt production.

In order to ensure the maintenance of high quality, stored grain will be subject to close scrutiny conducted by a selected aktiv.

Emphasis on Reducing Losses

Special care will be devoted during the harvest to measures aimed at reducing losses in grain athering. Controls, using unified standard methods, will be conducted daily by specially-designated officials in every agricultural enterprise. In okreses and Krajs, the harvest commissions will assess performance at least once a week. Moreover, the central harvest commission will regularly evaluate the results of loss control and the extent and effectiveness of preventive measures.

Broadly-developed socialist competition will during this year's harvest again be oriented toward high-quality labor, maximum utilization of harvest threshers without exceeding permissible losses, economy in propellants, and a smooth comprehensive course of harvest operations.

In the interest of reducing losses this year, full application and development of competition in eliminating losses in grain transport is considered especially important, and we will fully support the competition sponsored by the Socialist Youth Union under the slogan "Not a Grain Wasted." Full support will also be accorded to competition organized by the Central Committee of the Czechoslovak-Soviet Friendship League and the CSR Ministry of Agriculture and Food for the SK-5 and SK-6 combine crews.

In order to gain objective information, commission protocols on the completion of harvest operations will be drawn up in accordance with the "Methodological Instructions for a Unified Approach to Grain Harvest Control and Preparation of a Balance Sheet of Grain Utilization in the CSSR in 1980." The aim of this measure is to achieve a unified approach to the preparation of harvest reports in all agricultural enterprises.

At all levels of management in agriculture, the fodder industry, and agricultural enterprises processing grain for food production, we will apply principles this year of binding procedures in management, beginning with the earliest days of the harvest when harvested grain figures will be recorded.

Not Only the Harvest Proper

An indivisible component of harvest operations is the gathering and storage of straw in the shortest possible period of time. Quality straw plays a more important role each year in securing the cattle fodder base. This area is the subject of intensified effort and measures, especially with regard to organization of a smooth process of grain and straw gathering, which should be applied to the maximum possible extent. We have a good deal of experience in this area, especially in the application of the Ipatov method, which under our conditions has been found beneficial. Last year we harvested an area of over 450,000 hectares using this method.

Following the good experiences of last year, we are devoting great care to the seeding of stubble-field secondary crops with application of substantially better type composition for which prerequisites were created

in the seeding. Stubble-field mixtures will be seeded in the CSR on at least 260,000 hectares, i.e., 8 percent of arable land. The overall extent of secondary crop cultivation will thus grow this year to 11 percent of arable land.

Labor accumulation in the course of the harvest places great demand on organization and overall operational management toward full utilization of harvesting techniques. In consonance with this requirement, there will be uninterrupted operations during the harvest in services enterprises and purchasing organizations, especially in repair operations, spare parts sales, and receipt of grain at state inventories.

An inseparable component of harvest preparation and implementation must be consideration of and readiness for setting up measures for safety for workers, health protection, caring for them, as well as ensuring fire prevention measures. This whole area will be regularly monitored and assessed at all levels of agricultural management.

During the harvest, in cooperation with the trade sector, we must also ensure smooth supply to the market of early potatoes, the outlook for which is hopeful. By the end of June, domestic production of this crop supplied the market with over 6,000 tons. This demands that all producer regions consistently fulfill all operational tasks in potato purchases and, before the harvest, build up a sufficient reserve which would guarantee that, in case of weather deterioration, the market would still be satisfied.

In hops-producing regions, everything must be done, in terms of organization, materials, and technology, for a successful hops harvest. Preparations are under way for housing, feeding, and providing cultural activities for 38,250 brigade workers who will be helping with the harvest. By the same token, everything is being readied in harvest technology for smooth, effective operation, as well as for post-harvest hops processing. The aim is to gather this export crop in the best possible quality, with maximum economy, and minimum losses.

During the harvest we must also secure timely gathering of early fruits and vegetables for direct market supply and for the canning industry. Based on experiences of past years we ensure, in cooperation with the national committees, sufficient numbers of brigade workers, and timely transport and distribution, so that fruits and vegetables can be made ready for the market in appropriate quality and in a manner ensuring that all regions are supplied evenly.

Even though the attention of managers and technicians is rightly focused on the grain harvest, we must not for a moment disregard animal production. Since the beginning of this year, we have been exceeding the plan in milk purchases by more than 96 million liters, i.e., 5 percent. Compared with the same period last year, we have produced roughly 160 million liters more. Recently, we have been exceeding the plan in the purchases of slaughter beef and pork products. In the first half of this year,

pork purchases were fulfilled roughly by 49 percent of the annual plan. Egg purchases are being successfully met and in the timed plan there was an excess of 60 million.

The good trend in animal production must be ensured even during the harvest and fall operations. We expect a greater effort by all zootechnicians, animal tenders, as well as those whose responsibility it is to provide adequate supplies of fodder. The basic prerequisite still lies in regular daily deliveries of green fodder and maximum utilization of pastures. The services of the STS and OZS must devote more attention in the summer period to milk refrigeration equipment. The first duty during the third quarter will be fulfillment of animal product purchases, especially slaughter beef and pork, which must be regularly monitored and assessed by the management of agricultural enterprises, in addition to their demanding tasks in the organization and conduct of harvest operations.

In closing, I would like to express my appreciation to party bodies and organizations, workers of the national committees of all levels, and organizations of the National Front, for their effective assistance in the gathering of hay, and simultaneously voice my conviction that, in the harvest of grain, vegetables, and fruits, they will again assist the agricultural enterprises in the fulfillment of their responsible task, namely, ensuring the needs of the market and the processing industry, thus contributing to a high standard of living for citizens of the Czechoslovak Socialist Republic.

MAY 1980 ECONOMIC RESULTS PUBLISHED

Prague HOSPODARSKE NOVINY in Czech 27 Jun 80 p 2

[Article by Federal Statistical Office: "Report on Plan Fulfillment, May 1980"]

[Text] The development of the national economy showed the following basic tendencies in May:

--in industry, the largest increase over the same period last year was in deliveries for export to nonsocialist countries; deliveries for export to socialist countries and for production use and operations increased more slowly; sales for domestic trade remained at roughly the level of last May; the planned production tasks were fulfilled in May;

--in the construction industry, the plan for construction work was not fulfilled in May;

--in agriculture, milk procurement considerably exceeded last May's level;

--public goods transport handled the prescribed transport tasks well in May.

Centrally planned industry exceeded its planned delivery quotas in all sales areas in the period January-May 1980. The greatest overfulfillment of enterprise plans was achieved in deliveries for export to nonsocialist countries, amounting to 11.5 percent at FOC [free of charge] prices (3.5 percent at wholesale prices); deliveries for export to socialist countries overfulfilled the plan by 8.3 percent at FOC prices (5.6 percent at wholesale prices); deliveries for domestic trade exceeded the plan by 2.4 percent at retail prices. Sales quotas for production use and operations were 101.3 percent fulfilled by the industrial enterprises, while delivery quotas for investment were 107.8 percent fulfilled at wholesale prices. Deliveries in all the economic areas of sales were higher in the first 5 months of this year than in January-May 1979.

The indicators designated for current monitoring of plan fulfillment by enterprises were fulfilled during January-April 1980 by 404 organizations (i.e. by 45.9 percent of the total number of enterprises for which these indicators were designated). In the enterprises for which indicators of sales structure were designated, overall the plan was exceeded for all indicators except deliveries for selected construction projects from departments of the federal ministries of Metallurgy and Heavy Engineering, and General Engineering. In addition, the plan was not fulfilled by the organizations which are evaluated in terms of the indicator of expenditures per koruna of adjusted output.

With the exception of a certain worsening in April, the results achieved as regards total and material expenditures per unit of adjusted output in the operation of enterprises in the industrial departments have been better since the beginning of the year than the figures assigned by the annual state plan.

In agriculture, thinning of sugar beets has continued, and as of 12 June it had been done on almost 85 percent of the total acreage. Progress in harvesting perennial forage crops, however, is lagging behind the multi-year average. As of 12 June, 33 percent of the planned area had been harvested. The harvesting of fodder from meadows is just beginning, and faster progress is prevented by slow growth. In livestock production, an increase in the productivity of stock continues, manifesting itself primarily in increases in milk yield and average egg yield. The time plan for procurement over the 5 months was 104.3 percent fulfilled for slaughter poultry, 104.1 percent fulfilled for milk and 102.7 percent fulfilled for eggs. The time plan for procurement of slaughter animals was not fulfilled, and a low fulfillment level was posted in particular for slaughter hogs (97 percent).

Public goods transport dealt with the prescribed tasks well in May. The total amount of commodities transported was 794,000 tons, or 1.5 percent, above the planned level. The planned tasks in railway transport were also fulfilled by Czechoslovak Motor Transport [CSAD]. From the beginning of the year until the end of May, the public goods transport system carried 254.4 million tons of commodities, 0.7 percent more than the assignment for this period in the detailed plan. Railway transport 99.4 percent fulfilled its planned transport tasks for January-May; the shortfall was 736,000 tons of goods. The planned figure for commodities carried by the Czechoslovak Railways overall was 98 percent fulfilled for the 5 months; the plan for average daily tonnage was 98.1 percent fulfilled by the carrier units.

The construction industry failed again in May to fulfill the monthly segment of the enterprise plans for construction work. The quantity of construction work carried out with the organizations' own workers, amounting to Kcs 7.4 billion, represents 98.7 percent of the May plan and is 0.6

percent below the same month last year. Average daily output increased by 9.3 percent. Since the beginning of the year, the amount of work done with internal resources [ZSV] has amounted to Kcs 31.9 billion, 37.4 percent of the annual plan assignment and 98.9 percent of the enterprise plan segment for January-May. The number of construction enterprises not fulfilling their production plans increased compared with the preceding period: during the first 5 months of the year the enterprise plans for work with internal resources were not fulfilled by 147 enterprises, more than 60 percent of the total number. A low level of plan fulfillment was attained in contractor residential construction. Overall, during the 5 months the contracting construction enterprises turned over 14,460 apartments, 15.6 percent of the annual plan figure and 90 percent of the planned number for January-May.

The rate of increase of construction work carried out with the organizations' own workers during January-May was 103.9 percent of the figure for the same period last year; the figure in the annual plan is 104.5 percent. Average daily output increased by 4.9 percent during the 5-month period. Fulfillment of the set of indicators designated for current monitoring of plan fulfillment was variable in January-April. All indicators were fulfilled by about 18 percent of the construction enterprises. Good plan fulfillment was achieved in priority tasks and centrally reviewed projects and in projects in priority areas. There is still latent potential for fulfillment of the plan for decreasing expenditure levels.

In capital construction, during January-April investment work and deliveries (other than project Z and other self-help work) worth Kcs 33.9 billion were performed. According to estimates for May, the total quantity of investment work and deliveries for the 5 months was Kcs 43.9 billion, 4.9 percent higher than the same period last year. Larger increases were posted for deliveries of machinery and equipment (5.2 percent) than for construction work (4.5 percent). By the end of May about 31.4 percent of the capital construction in the annual plan had been completed.

In foreign trade, during January-May 1980, 37.0 percent (at current prices) of the year's plan assignment for export to socialist countries was fulfilled, as were 36.1 percent of the plan for export to socialist countries, 33.7 percent of the plan for import from socialist countries and 36.8 percent of the plan for import from nonsocialist countries. The rate of increase of exports to and imports from nonsocialist countries posted during the 5 months was affected by continuing price increases, which are larger than those planned for the year. In trade with socialist countries, the planned pace for the year was exceeded by export. The ratio of FOC prices to wholesale prices during the first 4 months of the year was more favorable than the planned figure for the year in export to nonsocialist countries, while in export to socialist countries it did not reach the annual-plan value.

Basic Indicators of Development of National Economy in May 1980
Increments Over Comparable 1979 Period (in percent)

	May	Jan- May 1980	Federal Plan[1]
Sales:			
Capital deliveries total in wholesale prices	*	1.1	-4.5
Domestic market deliveries at retail prices	*	4.8	4.8
Exports to socialist countries			
at wholesale prices	*	5.4	3.5
at FOC [free of charge] prices	*	9.3	8.0
Exports to nonsocialist countries			
at wholesale prices	*	8.5	3.9
at FOC prices	*	31.3	14.5
Other sales for production use and operations at wholesale prices	*	40.0	*
Industry:			
Gross production	-2.4	4.2	3.7
Average number of workers	0.8	0.8	0.8
Labor productivity	-3.2	3.4	3.2
Construction:			
Construction work completed with internal resources	-0.6	3.9	4.5
Average number of workers	0.3	0.3	0.4
Labor productivity	-0.9	3.6	4.1
Housing units delivered by contracting enterprises	-7.5	1.6	16.8
Procurement:			
Slaughter animals (including poultry)	-3.7	-1.8	0.4
Milk	8.6	8.0	1.8
Eggs	-2.1	4.1	3.2
Retail Turnover:			
Of the main trade systems	3.2	5.9	2.2[2]
Foreign Trade:[3]			
Exports to socialist countries	3.5	9.3	8.0
Exports to nonsocialist countries	11.9	29.1	16.5
Imports from socialist countries	-6.5	-1.0	8.9
Imports from nonsocialist countries	37.9	28.9	8.0

[table continued]

	Apr	Jan-Apr	
Completed Investment Projects and Deliveries			
(less action Z and other self-help)	6.2	6.8	2.5
including: construction	2.9	6.8	6.3
machinery and equipment	10.4	6.5	-2.0
National Income[5]	5.7	5.8	5.4[4]
of which: wages	4.6	4.8	4.0
Actual Monetary Expenditures[5]	9.8	7.9	3.7[4]

[Key to table]
1. Increments compared to expected actual 1979 results with the exception of work indicators in the industry.
2. All trade systems
3. Data on actual results refer to actual transactions and do not include unplanned actions in the framework of cooperation, unplanned reexport trade operations, barter, tied trade transactions, etc.
4. Including estimated interest for loans
5. Monthly data calculated according to the treasury plan of the Czechoslovak State Bank.

In domestic commerce, this May the pace of retail turnover in current prices was slower than in April, resulting among other things from a smaller number of sales days. The organizations belonging to the main trade systems achieved a retail turnover of Kcs 17.5 billion in May. The rate of growth of retail turnover was 103.2 percent of the figure for May 1979 (103.4 percent in the retail network and 102.3 percent in public dining facilities).

National income increased in January-April 1980 by 5.8 percent over the same period last year, while wage income was up by 4.8 percent. Actual money expenditures during the first 4 months of the year were up 7.9 percent over the same period last year.

Personal savings accounts grew by Kcs 0.6 billion between 15 April and 15 May. Total savings as of 15 May 1980 were Kcs 151.3 billion, Kcs 3.2 billion higher than a year ago.

The money supply was Kcs 42.6 billion as of 31 May 1980.

PETROCHEMICAL COMBINE EXPANSION, RATIONALIZATION DISCUSSED

East Berlin EINHEIT in German Vol 35 No 7/8, Jul-Aug 80 signed to press 13 Jun 80 pp 729-733

[Article by Dr Horst Martens, director, Friedrich Engels SED Bezirk School, Frankfurt/Oder: "Rationalization in the Interest of the Workers"]

> [Text] Under socialist production conditions, socialist rationalization is being carried out with people for their benefit. Their active participation in the process is a decisive criterion. Examples from the PCK [Petrochemical Combine], Schwedt, demonstrate what tasks there are to accomplish here, how the working people are being persuaded through ideological work to participate actively and which problems are being mastered in the process.

Today there is probably no doubt anywhere that the acceleration of scientific-technical progress -- to a great extent through the introduction of modern technologies into production -- is ensuring dynamic production growth for the economy, a significant rise in the quality and effectiveness of labor. The increasingly more effective use of the results of science and technology by the working people and the growing output of each individual dedicated to this end are proving to be decisive prerequisites for the continued realization of our program of full employment, public welfare, growth and stability.

Thus, by following the path of socialist rationalization in our country, we are taking the most productive and at the same time the only possible route toward attaining the maximum effectiveness and quality of labor. "The most important thing," emphasized Comrade Erich Honecker at the 12th Central Committee Plenum, "is to increase substantially our country's economic productive capacity. We are convinced in this regard that the communists will exert their influence everywhere to accelerate scientific-technical progress, the decisive link in the chain leading to the further stable and dynamic development of the economy of the German Democratic Republic."[1]

According to the social purport of rationalization, it is the complete opposite under capitalist conditions from what it is under socialist conditions, since here the people "become for the first time the actual and conscious masters of nature, because and since they become masters of their own socialization."[2] "Given the certainty of full employment, [rationalization] helps improve working and living conditions for workers and white-collar employees... . It improves production conditions, and, above all, rationalization is carried out jointly with the working people. Supported by this community of interests, the whole force behind rationalization must be utilized, and we must rationalize in at least as grand a style as the capitalists are doing."[3]

It is a rationalization that is being carried out by the working people for the working people, a process in which the creativity of the working masses can find full expression. We cite in this connection some experiences gathered by the main enterprise of the Petrochemical Combine, Schwedt, where rationalization has been going on since 1978 on a scale such as has never been experienced.

New Avenues Pursued

The main enterprise of the Schwedt Petrochemical Combine is a highly modern chemical enterprise with more than 8,500 employees. With the aim of increasing the effectiveness of the economy as a whole, this plant is being expanded through the construction of two new large-scale chemical installations: an installation for the production of protein fodder yeast and a cracking and aromatics complex. They are designed to further refine the petroleum cracking process and make better and more effective use of petroleum. Both installations will begin operating in 1981-1982, thus doubling the enterprise's present capital assets. The enterprise was charged with obtaining the 2,400 workers needed for these new installations through the rationalization of jobs in its own plant.

A rationalization project of this magnitude could not be accomplished on the basis of previous methods and experience (rationalization in segments of years, for example). Rather, the objectives required a qualitative rethinking, a critical examination of past experiences and a search for new solutions; they required the drafting of a rationalization strategy. Used in this process were Soviet experiences gathered from the "Polymir" production association in Novopolotsk, Vitebsk Oblast (Belorussian SSR), with which Frankfurt/Oder Bezirk has maintained a close partnership for years. The Soviet comrades in this same kind of enterprise were faced with similar problems years ago. They had to open up new installations with no manpower reserves. They therefore developed a long-range rationalization strategy known as the Novopolotsk Method. With the aid of this method, they were able to cut back their workforce by 20 percent and assign these workers to the new installations.

On behalf of the Frankfurt/Oder SED Bezirk Management, the Schwedt comrades studied the ideas obtained there and applied them creatively. At the beginning of 1978, the general director and the party management of the main enterprise of the Schwedt PCK presented their rationalization strategy, which has since then become known far beyond the enterprise and the bezirk under the name "Fewer Produce More."

A conception of the task of obtaining 2,400 workers through rationalization within the period from 1978 to 1981-1982 was initially mainly a process of discussion, one of working out a uniform standpoint on the range and magnitude of the requirements and on the resulting demands upon the political leadership work of the party and the state management, upon conduct of the socialist competition. It turned out that an improvement in the quality of political-ideological work was needed if appropriate attitudes and convictions were to be inclucated. On the basis of this recognition, the main enterprise of the Schwedt PCK is and has since 1978 been pursuing mainly the following avenues for rationalization:

Centralization and concentration of management and production sectors, together with a pervasive rationalization and partial reordering of work processes in management, control and production;

Expansion of service sectors in the installations by making further changes in the existing division of labor and work organization;

Establishment of a new regime for starting and stopping processes, together with the drafting of staffing norms for the normal operating mode as well as for the peak operating mode of the installations;

Expansion of the functions of the labor collectives at the installations by transferring certain maintenance and repair responsibilities;

Increase in the effectiveness of planned investment measures, among other ways by minimizing staffing norms.

Using these means, it will be possible to gain 1,763 workers through specific rationalization measures in the existing installations. In addition, interdisciplinary WAO [scientific work organization] collectives working on investment projects are being used to eliminate 637 workers originally called for in the staffing norms. These personnel will make it possible to operate the large new installations safely while observing all safety regulations. Mastery of the complex processes leading to the attainment of this lofty goal will require their proper central integration and strict management by the general director in cooperation with the party management. Indeed, it will require staff methods of leadership at the various levels, methods that are now in use in Schwedt.

Gain the Conscious Participation of the Working People

It is obvious that such a complex process requiring precise scientific management cannot be carried out successfully without active participation by the working people, without their conscious inclusion -- in other words, without a broad realization of socialist democracy. Schwedt's experiences confirm wholly and completely a basic truth in our lives: Socialist democracy is part of the essence of socialist rationalization and its implementation. New dimensions in socialist rationalization are virtually inconceivable without the conscious participation of those who do the producing. It takes comprehensive teamwork to realise such a rationalization strategy, teamwork in which the scientist is in demand just as much as the worker or master workman with long years of practical experience. It requires the participation of all social forces in the enterprise as an essential prerequisite for accomplishing the tasks at hand. The issue is real codetermination, and even more than that, a real sense of shared responsibility based on factual knowledge, on a deep understanding of the need for rationalization in new dimensions, on a greater and greater awareness of social interrelationships.

In this context, let us discuss some experiences from the fertilizer production sector in the main enterprise of the PCK, Schwedt. This part of the enterprise was developed as a model sector, since the scope of the objectives made it impossible in such a highly complex combine enterprise to begin with rationalization at the same time in all sectors, thus making it necessary to proceed gradually.

Complete documentation on rationalization measures in this production sector has been available for some time; scheduled projects for the rationalization of jobs are being developed in five other sectors. The complete enterprise documentation is to be submitted to the 10th SED Party Congress.

Intensive work was done in the fertilizer sector, as in the entire plant, to completely convince all the working people of the need for rationalization and to discuss with them their personal part in it as well as all the problems that are involved. Issues like these came up: the necessity of leaving a labor collective after an association of many years in many cases; of continuing one's education after working hours; of adapting to the rhythm of a different shift; and also, in many instances, an honest concern about dealing with the new requirements. It took close collaboration among party organization, state managers, trade union and youth organization to clear up these kinds of questions, reaching every labor collective and every worker.

To be sure, this process was not without conflict. Between April and June 1978 in the fertilizer sector alone, notes were kept on more than 600 discussions and consultations. These were frequently debates uninterrupted by applause, debates which gradually brought the discussion around from the why's to the how's. Tied in with this was a broad publicity

campaign using the enterprise newspaper and radio system, lecturers' councils, training facilities and leaflets. Every question posed in the debates was recorded. Then it was decided which questions were of general interest and would be answered using public relations means, and which were individual questions to be cleared up in personal interviews. There were as many as seven discussions with some colleagues; their families were often included, since a change of shift or participation in a lengthy night course, for example, are indeed matters that also concern the family.

Regardless of how indispensable these measures were to success, the inclusion of the working people was by no means limited to this. New forms of real cooperation by workers and members of the intelligentsia were developed for the purpose of realizing the rationalization strategy. Especially successful was the establishment of an honorary Council for Scientific Work Organization as well as WAO collectives in the different sectors. Belonging to these collectives are representatives of party organizations and other social forces in addition to specialists, state managers and practical experts. Working in the fertilizer sector is an honorary WAO collective with five work groups. One of these five, for example, deals with public relations and another with matters of personnel development and further training.

In the course of a few months, a comprehensive WAO study produced the following results: With an employee staff numbering somewhat more than 400 in this sector, by 1982 there can be a gradual elimination of 38 jobs that are occupied by 91 workers, or 21 percent of the staff. Since production will continue to increase at the same time, labor productivity in these installations will rise to an average of 138.4 percent. Of the 91 workers, 19 are working in management. Here especially, the aforementioned centralization and concentration of management and production sectors will be having a favorable effect.

Active Role of WAO

A total of 340 workers -- about 85 percent of those employed there -- were actively included in the most varied ways in the drafting of the comprehensive WAO study. Some were assigned special duties by way of innovator agreements. The workers put down in detail in the study those technical, technological, work-organizational and other measures that have to be realized if manpower retrenchment is to be truly assured, while permitting no deterioration of working or living conditions and fully guaranteeing labor and production safety.

These facts constitute a characteristic expression of the realization of socialist democracy in everyday life; they express the fact that socialist rationalization is a creative process which makes great demands upon the individual, which encourages and challenges him completely. It becomes apparent here that socialist democracy does not exhaust itself solely in

real codetermination; rather, it is profoundly linked with the development of socialist individuals also by way of further education and training. Needed here was a qualifying process of a breadth and depth never experienced before, one which the fertilizer workers initiated with the reflection that an increasing level of qualifications makes possible greater flexibility of job assignments, and that job retrenchment requires a greater willingness to accept responsibility, a situation that also demands a background of knowledge. They wrote: "Of course we do not want to and must not expect anyone to take on more than he is actually capable of as regards his knowledge and abilities. On the other hand, we nevertheless consider it absolutely normal to challenge fully all the abilities and performance reserves of the individual, also for the development of his personality."[4]

The 91 workers whose jobs were targets for retrenchment were shown a catalog of job offers from which they could select a job in the new installations that matched their qualifications and productive capacity and their physical and mental endurance. Each position is linked to an appropriate qualifying program which is now being carried out in various forms through enterprise facilities for education and advanced training.

There are also personal training programs for those who will be staying in the existing installations but will have expanded service zones. These plans provide that a colleague qualify as primary installation operator wherever two installations are operating, for example. This would reduce to 20 percent the passive time periods recorded by an operator, periods which previously amounted to about 70 percent of an operator's working hours. Included in the active time periods and added to the expanded service zones are specific maintenance duties to be performed while the installations are operating. This also requires appropriate training. The education and training sessions generally take place outside of working hours.

Results Speak for Themselves

How has the level of qualifications changed in the fertilizer sector? Before the rationalization measures were instituted, a single employee was capable on the average of meeting the demands of between 2.9 and 4.9 jobs; afterwards, this average was between 4.9 and 6 jobs. This therefore signifies an enormous increase in productive capacity as the result of increased qualifications on the part of the workers.

All continuing education measures are aimed at developing a sense of responsibility, reliability, discipline on the job, initiative and creativity and at increasing the willingness to engage in a permanent program of continuing education. They therefore foster personality development among the working people, thus establishing decisive bases for making democracy a reality.

A closer scrutiny of this sector today reveals the following conditions: The sector presently has the lowest down-time levels; the collective as a whole has strengthened itself; an optimistic, healthy, confident working atmosphere prevails.

Precise job analyses that led to altered job structures and improved working conditions also made it possible to increase by 1 percent the proportion of jobs for women.

All this underscores the fact that socialist rationalization is inseparably linked with socialist democracy, is objectively tied to the process of increasing flexibility of assignment and development of the abilities and skills of the working people. No person is or will become superfluous. As a rule, each one is accorded greater responsibility. Socialist rationalization can be implemented only if the creative thoughts of every working person flow into it, only if every important issue is discussed with each one, only if each one participates actively and his ideas are used. It is also in this way that the necessary confidence in the social objective is strengthened.

Friedrich Engels said in his work entitled "The Evolution of Socialism from Utopia to Science": "The process of men's own socialization, which hitherto was as though forced upon them by nature and history, now becomes a free act on their part.... Not until then will men begin to make their history themselves, with total awareness; not until then will the social causes set in motion by them begin to have predominantly and to an ever-increasing degree the effects that are also desired by them. It is mankind's leap out of the realm of necessity into the realm of freedom."[5]

Our practice of real socialism makes clear that this leap into the realm of freedom is a revolutionary process, one which encourages and totally challenges man, a process whose essence is the development and conscious expression of the socialist personality and which makes very great demands upon the political leadership of our party. It demands the most meaningful, the most efficient and the most effective use of that which is most valuable -- the human being -- and it demands of the working people their creativity, ideas and the great and conscious use of their whole personalities.

COMBINE SYSTEM, NEW MANAGEMENT PRACTICES SPUR GROWTH

Oslo ARBEIDERBLADET in Norwegian 25 Aug 80 p 14

[Article by Dag Halvorsen: "Economic Optimism in the GDR"]

[Text] The results from the first half of 1980 are so good that GDR economists now once more look more optimistically on the future. The output of industrial goods rose 5.7 percent against a planned mere 4.5 percent. But progress costs. Investments went up nine percent, more than three times as much as the planned amount. On the other hand, net profit rose only three percent against a planned four percent. This was due to price increases which, however, did not include everday goods.

The optimism cannot cover up the fact that there is comparatively less for consumers, both in the GDR and in the other COMECON countries. In the Eastern economic cooperation organization coordination of the national five-year plans which begin on 1 January 1981 is now being prepared. All are betting on somewhat lower growth and on a slower increase in the standard of living than in the 70's. The world crisis which is throwing its shadow over foreign trade and energy problems has also hit Eastern Europe.

But the East Germans occupy first place in the East. This is shown both by these figures and other statistics which, for one thing, reveal that the GDR has been more than fulfilling its ambitious housing construction program, while the Czechs and especially the Poles are lagging behind.

Housing is still very inexpensive. Housing expenses of under five percent of one's pay are usual. Sixteen billion of the State budget's 140 billion go toward subsidies. Of this amount seven billion are used to hold the price level for everday goods constant and the rest is used mostly for subsidizing housing and transportation. In addition come increasing contributions to families with children. All this contributes to a secure social standard which can only be dreamed of elsewhere in the East, and for that matter in a number of Western countries.

The reverse side of these triumphs is of course the enormous subsidies, which are criticized by more market-oriented economists in other Eastern

countries, too. They think that it is possible to arrive at a more realistic price level. But their colleagues in the GDR say that they know exactly what goes toward social subsidies and that industrial prices have changed since 1976. They have increased considerably, in pace with the development in the world market, so that businesses are operating with relatively realistic prices for materials, goods and services. This has, by the way, been a traditional sore point in Eastern economics.

Moreover, prices on a number of consumer goods have gone up. Suddenly bedclothes disappeared from shops, only to just as suddenly turn up again with almost 100-percent higher prices. A spray can which cost M8 went up to M14.50. But people have money. Japanese color televisions for M5100 were quickly sold out. There continues to be more money than goods in the GDR although the disparities are not so flagrant as in Poland. There have at times been problems with getting meat and there are lines outside shops which sell finer goods, but the supply is largely satisfactory, as seen by Eastern eyes, in any case.

Productivity increased better than planned in 1980. The social standard and better organization in daily life than in the other Eastern countries can influence the promotion of productivity. One does not have to use a half a day to go to the doctor or to go shopping, such as in Poland; there everyone who can shirks as much as he can. But the most important reason, we hear tell, is better organization in industry.

In reality it is a question of a new East German economic reform which has developed gradually since 1976. The key positions in industry and construction are now occupied by, for the time being, 129 so-called combines. They now include all branches and consist in most cases of a number of concerns. The role of ministries in daily operations has been considerably reduced. The way from the combine management and to individual firms is shorter. This has resulted in the fact that capable professionals, who are now found primarily in the management of combines, have gained wider latitude and can operate more effectively. This is an advantage which experts in the East and West agree on.

The West Germans especially, of course, follow closely the development of the GDR's economy. The first results are encouraging; nevertheless the new management teams in the GDR are faced with very difficult tasks. The level of investment must be kept under control. It is necessary to save on energy and, not least, on materials; besides there is a potential here. Combines will also play a more independent role in foreign trade and have their own research apparatus with direct contact with academic institutions.

The combines are also direct partners in the planning commission. In the GDR they continue to believe in a plan, in setting concrete goals for what must be achieved in five years, goals expressed in tons, marks and pfennigs. But we understand that it is rather a question of a detailed

forecast. In our times one cannot be the slave of a plan; also, yearly plans must be corrected if economic development makes this necessary.

There is much to indicate that the GDR is in development toward greater efficiency and a more intelligent management system. But the trade unions continue to have primarily social tasks. The GDR is a managed society; the question of an industrial democracy is not on the agenda. On the other hand, even the most critically inclined admit that the management is quite occupied with protecting the social standard for the average East German family. It is a system which harkens back not only to Marx, but also to Bismarck, who wanted to have order, but also introduced Europe's first modern social legislation.

ECONOMIC RELATIONS WITH IRAQ DESCRIBED

Budapest FIGYELO in Hungarian No 31, 30 Jul 80 p 7

[Article by Janos Menyhart: "Our Most Important Partner"]

[Text] The economic relations between the Hungarian People's Republic and the Republic of Iraq have grown steadily in the period since the Iraqi Revolution of 17 July 1968. But this growth was especially dynamic in the course of the 1970's. During this period the two states concluded several agreements, which created a favorable atmosphere for cooperation and for expansion of trade. In the course of the past few years the Republic of Iraq has become our leading trading partner among the developing countries.

Doubled Since 1977

In addition to several joint commissions on the ministerial level (such as those on agriculture and food industry, irrigation projects, etc.), there is also a Permanent Joint Commission on Economic Cooperation, which was established in 1972 for the purposes of promoting economic cooperation between the two countries.

The complementary nature of the Hungarian and the Iraqi economies, the large-scale Iraqi economic development programs financed by the rapidly growing oil revenues, and the level of development of the various branches of Hungarian industry have all been instrumental in creating favorable bases for the further development of these relations between the two countries.

As evident from the following graph, between 1972 and 1979 the value of the bilateral exchange of goods has multiplied 15 times, and the composition of the goods has also changed significantly. Up to the early 1970's most Hungarian exports consisted of consumer goods. Since 1972, however, 50 to 60 percent of Hungarian exports are made up of machine industry products. Hungarian enterprises have participated and are still participating in several significant Iraqi economic development plans. As an

The Development of Hungarian-Iraqi Foreign Trade

example, the Babolna State Farms have delivered equipment for 10 large poultry farms geared toward the production of eggs and poultry. Up to now Hungarian drillers have put into operation 19 oil wells in the oil fields of Rumayhan and Jambur. Deliveries of Hungarian food industry equipment (e.g. canning lines, cold storage facilities, slaughterhouses, mills, etc) are also significant. Mention should also be made of Hungarian technical involvement and the delivery of Hungarian equipment for the processing of dates.

Investment Goods for Industrialization

In 1974 Hungarians were instrumental in putting a bus assembly plant into operation in al-Iskandariyah. Their contributions included the delivery of bus body parts, as well as the giving of technical advice. Today, this plant satisfies virtually all of Iraq's needs for buses. In addition to the above, up to 1976 the Hungarian auto industry had also delivered to Iraq nearly 700 buses which are now being used not only in Baghdad, but also throughout the various provinces. There is also a lightbulg factory in Taji, that has been manufactured by the Egyesult Izzo-Tungsram. A sizable portion of the electrification programs of Iraqi villages is being carried out with the aid of Hungarian substations. Recently we have also delivered lime works, as well as sulphur processing equipment. Many Iraqi health centers are using Hungarian X-ray machines and other medical equipment.

In addition to deliveries directed toward the cause of industrialization, Hungarian exports are also playing a role in supplying raw materials to the Iraqi economy, and consumer goods to its population. (These include rolled steel, aluminum products, chemicals, tomato pastes, various textile products, etc).

Most of Iraq's exports to Hungary consist of crude oil. But Iraq has also supplied for years the country's needs in edible dates. The products of the developing Iraqi industry—such as date syrup, textile products, etc—are being gradually introduced into the Hungarian markets. In the course of 1980, market weeks are also being planned both in Baghdad and in Budapest. The new Iraqi Five-Year Plan for the years 1981-1985, which is currently in the planning stage, calls for the dynamic further development of the Iraqi economy. The total sum of the planned investment exceeds $50 billion. (The projected investment for the period between 1976-1980, to be completed this year, is approximately $49 billion.) The completion of the investment plans presumes an increase in the imports. As against the earlier annual average of $4 - $5 billion, the Iraqi imports for 1980 will probably exceed $10 billion.

The above sketchily outlined conditions afford favorable opportunities for the further development of Hungarian-Iraqi economic relations, as well as for a vigorous increase in the exchange of goods. It is particularly significant that Iraq pays with cash even for complete equipment.

We must also mention that the special features of the Iraqi markets, with the rise of the 1979 Hungarian export level, place increasing demands upon Hungarian export companies, as well as upon the Hungarian industrial establishment in general. One of the basic principles of Iraqi economic policy that has been enunciated by the Iraqi Government in the course of the past few years is that the country's development must be based on the most advanced technology available. Our industry is able to satisfy this

demand in numerous areas. But in order to insure the required technological level, we must also consider joint deliveries and cooperative ventures with companies from various Third World countries. (There are already numerous successful precedents for such undertakings.) It is very important that we should observe delivery obligations exactly and in line with the deadlines.

Possibilities for Increasing Exports

In assessing the above factors as a whole, our export possibilities appear favorable, especially in the machine industry area. In light of the expected Iraqi development plans and Hungarian delivery potentials, our best chance for participating in these developments exists primarily in such areas of the machine industry as are listed below. This is all the more so since--in accordance with Iraqi needs--while delivering our machines and our equipment, we can also supply Iraq with the essential construction work, as well as with the Hungarian technical know-how needed for the installation, operation and servicing of this equipment.

--equipment and complete machine systems for farms (e.g. farms for raising poultry, cattle, and vegetables and other plants);

--irrigation and water management (e.g. water works, water purifiers);

--food processing (e.g. cold storage facilities for meats and fruits, mills, slaughterhouses, canning lines);

--educational centers (e.g. trade schools, secondary schools, and institutions of higher learning);

--vehicle industry (e.g. bus parts, bus assembly, special trailer trucks, motor trains, diesel engines for railroads);

--telecommunication equipment (e.g. village telephone exchanges, URH equipment and networks, pulse code modulating equipment, etc.);

--electrification (e.g. power station equipment, substations, transformers, cables);

--complete hospitals, medical instruments, rural health centers;

--chemical equipment (e.g. pharmaceutical plants, varnish and paint factories);

--harbor equipment;

--oil well drilling, oil pipelines, automatics and telemechanics;

--aluminum industry;

—other equipment, including lime works, brick factories, foundry equipment, cable factories, garment factories, etc.

Hungarian industry is able to assure the delivery of complete systems in an ever increasing number of areas (e.g. agriculture, medical sciences, communications technology, and education).

It is still possible to increase the export of Hungarian food and other traditional products to Iraq (for example, medicines, rolled steel, aluminum semifinished products, metal mass produced goods, textile products, photographic materials, artificial leather, etc). We can also continue to count on the exportation of poultry products.

Technical Scientific Cooperation

In order to fulfill its large-scale economic development plan, the Republic of Iraq is counting increasingly upon the continued development of technical-scientific cooperation, and within it especially upon the aid of an increasing number of Hungarian experts, as well as upon the training of Iraqi experts in Hungary. Even though the technical-scientific cooperation between our two countries is only of a relatively recent origin, there are still many favorable developments in this relationship.

Under the aegis of this technical-scientific cooperation, today 37 Hungarian experts are employed in Iraq. (We are not counting the many hundreds of technical experts who are continuously on the scene in conjunction with the delivery of Hungarian equipment.) The number of Iraqi experts who are being trained in Hungary averages out to over 100 per year.

Within the confines of a more broad technical-scientific cooperation, Hungarian concerns were responsible also for having prepared the development plans for various agricultural establishments in Iraq. The high quality of Hungarian industrial, agricultural, hydraulogical, etc, planning, and the Iraqi development plans offer favorable conditions for a significant increase in the Hungarian-Iraqi technical-scientific cooperation.

In light of the good political relations between the two countries, and in view of the already existing economic ties and generally favorable relationships on the state level, as well as between individual companies, in the forthcoming period we can count on a rapid expansion of Hungarian-Iraqi economic cooperation.

VII NATIONAL CONFERENCE ON PIG IRON, STEEL PRODUCTION OPENED

Budapest KOHASZAT in Hungarian Nos 3-4, Mar-Apr 80 pp 100-103

[Opening address by Sandor Csepanyi, deputy minister of metallurgy and engineering]

[Text] In my address at the Conference of Metallurgists I wish to acquaint the esteemed conferees with the timely problems and tasks of Hungarian metallurgy, with special emphasis on our efforts to improve the quality of our products.

The workers of Hungary's ferrous metallurgy are striving at present to successfully complete their Fifth Five-Year Plan. Parallel with this activity, our enterprises and managing organs have begun to cooperate on defining the principal tasks of the Sixth Five-Year Plan. Already now, in 1979, we are encountering specifically the difficulties placed on us by changes in the world economy. Our problems in conjunction with the procurement of coke and alloying materials are growing. In the area of marketing, intensifying world-market competition sets ever-higher quality specifications for our products.

The requirements of economic effectiveness that our planned investments must meet are increasing considerably.

The workers and managers employed in ferrous metallurgy must ensure even in this more complex situation the continuity of metallurgical production and improvement of its economic effectiveness.

Reviewing the problems of the vertical interrelations in ferrous metallurgy, I wish to emphasize first of all the situation with respect to the quality of the charge in pig iron production. Nationwide the burden yield has been around 44 percent in recent years. As we very well know, this rate is among the worst, 15 to 16 percentage points lower than the good international level. One of our most important tasks is to raise our average burden yield as soon as possible, by increasing the Fe content and reducing the SiO_2 content of the charge.

Experiments conducted at the Technical University for Heavy Industry have confirmed that the available hematite can be concentrated successfully for agglomeration, through modern magnetic separation in a strong magnetic field. Relying also on these findings, we have begun negotiations with the competent Soviet organs, on building a jointly financed concentration plant in the Krivoy Rog area. At the same time we must also investigate the economic effectiveness of importing from capitalist countries ore that has an Fe content of 65 percent minimum and a low hydrated silica content.

As a result of the investments in ferrous metallurgy, undertaken or to be completed under the Fifth and the Sixth Five-Year Plan, Hungary's output of steel and rolled steel will increase in harmony with the economy's demand. In comparison with the 3.6 million tons produced in 1975, our steel output will be 4.0 million tons in 1980, between 4.3 and 4.5 million tons in 1985, and foreseeably 4.8 million tons in 1990, which will correspond to an increase of 33.3 percent over 1975. It will be expedient to round out these figures with the annual per capita output of steel. In Hungary this output is 360 kg at present, and we will not exceed the 450-kg figure even by 1990. International comparisons, based on the statistical data for 1978, show that the per capita steel output is 158 kg in Yugoslavia, 291 kg in Bulgaria, 541 kg in Austria, and 992 kg in Czechoslovakia.

Parallel with this the output of rolled steel also will increase but at a faster rate, thanks to continuous casting machines. We can expect a 47 percent increase in output by 1990 if we take the 1975 output volume of rolled steel to equal 100 percent.

As a result of investments, the fixed capital of Hungary's ferrous metallurgy and the investment costs during the individual plan periods will develop as follows: In comparison with 32.5 billion forints in 1975, the fixed capital will increase to 85 billion forints in 1990, which corresponds to an increase of 162 percent. Investment costs under the Fifth Five-Year Plan total 25.3 billion forints, and under the Sixth Five-Year Plan they foreseeably will reach a level of between 26 and 29 billion forints.

Let us examine the productivity of live labor. The steel output per worker in ferrous metallurgy will increase from 45.7 TPY in 1975, to 52.8 forints [sic] in 1980, an increase of 16 percent. This indicator of effectiveness is very unfavorable in the light of international comparisons, because it is only one-third of the present level in Sweden, one-fourth of the level in France, and merely one-seventh of the level in Japan, the recognized world leader.

To improve our economic effectiveness and to become more competitive, we clearly must reduce our consumption of energy and materials, raise the quality of our products, and increase the volume and number of our more profitable products. In its resolution of 20 October 1977, the MSZMP Central Committee strongly emphasized these objectives and urged the economic and more competitive transformation of the production structure.

In comparison with 1975, the value of ferrous metallurgy's gross output will increase 51 percent by 1990.

Among the implemented or proposed changes in the production structure we should single out the rise in the proportion of continuously cast billets in relation to the total output of crude steel. Our continuous casting machines processed 21.4 percent of the total steel output in 1975, and more than 30 percent in 1978. This proportion will rise at a slower rate in the coming years, reaching 36.5 percent in 1985, and foreseeably 55 percent in 1990. The construction of new steel mills generally involves the installation of continuous casting machines that increase rolling-mill capacity and significantly reduce energy consumption, providing a basis for reducing the production cost of steel and rolled steel. Naturally, also the existing steel mills are converting, one after the other, to this method of casting. In Austria, for example, the proportion of continuously cast billets will increase from the present 40 percent to 71 percent by 1981, and at the same time the quantity of alloyed steel produced by continuous casting will also increase.

An important task of Hungary's ferrous metallurgy is to supply manufacturing industry with steel products of suitable quality. Therefore we are treating as a high priority topic the improvement of quality, and development of the parameters that directly or indirectly are characteristic of quality. In general, total rejects at our plants have developed in a satisfactory manner: the proportion of rejects is relatively low and shows a declining trend. In some instances, however, a plant's total rejects conceal how the individual products' proportions of rejects develop, and for this reason we investigated the causes of rejects. Accordingly, 15 percent of the products investigated in 1975-1978 was characterized by a rising proportion of rejects; 52 percent had variable proportions of rejects; and 33 percent had declining proportions of rejects. The rising, high and varying proportions of rejects obviously indicate that a modern system of quality control, one that reduces the proportion of rejects purposefully and dynamically, by reacting immediately upon production, has not been introduced everywhere as yet. In many areas, quality-control methods merely of the recording type are used to attain even the traditional, good level of quality. One of our important tasks is to implement in practice as quickly as possible, with the wider application of computers and of the methods of mathematical statistics, systems of quality control that cover the entire production process and evaluate also the customers' experience. This is the more important because the enterprises that use ferrous metallurgy's products generally do not substantiate their complaints with specific data concerning the nature and extent of the defects. Although not worded precisely in most cases, the quality complaints of the enterprises that use ferrous metallurgy's products can be summed up as follows:

In the case of hot-rolled plate and sheet, the complaints concerned mechanical properties, internal defects--mostly lamination--and mistakes in grading;

In the case of cold-rolled sheet and strip the causes of complaints were mostly off-gage and off-size material, surface defects, and deviations of the mechanical properties;

Among the complaints against spiral-welded, butt-welded and seamless tubing we might mention particularly off-gage material and mistakes in grading;

Most complaints against hot-rolled bars, sections and forgings concerned off-gage and off-size material, internal defects, and mistakes in grading;

The causes of complaints against drawn, stripped and bright-drawn rods and wire were surface and internal defects, and deviations of the mechanical properties and grain structure;

Several users are dissatisfied with the steel and iron castings, mostly because of surface defects and off-size material.

In conjunction with improving the quality of the iron and steel products, however, it should be emphasized that these efforts must be considered also from the viewpoint of economic effectiveness. The costs of maintaining extremely low quality are small, over and above the basic production costs, but the subsequent costs of repairing the rejects and settling claims are substantial. If on the other hand we aim for extremely high quality, the costs of maintaining it will be substantial, at minimal reject costs, but the total production cost will nevertheless be high. Optimal quality, from the viewpoint of cost, can be found somewhere between these two extremes. Taking all this into consideration, on the basis of the realistic quality complaints of manufacturing industry that processes iron and steel products we may say that the quality of many of our products has to be improved.

We will commission two converter steel plants during the first years of the Sixth Five-Year Plan. We expect our metallurgical workers to become well trained at these plants, for the rapid introduction of a technology that is new in our country, and to solve the production of steels of uniform quality that have narrow tolerances with regard to their composition. It will be the task of the managers in iron and steel production to carefully select the installations that can contribute significantly toward improving the quality of our products. At the Danube Iron Works, for example, a modern installation will be commissioned already this year, for ladle finishing. The "Scandinavian lance" process is based on blowing a powdered deoxidizing agent or flux into the melt, by means of an inert gas, to lower the sulfur content below 0.005 percent and to ensure a very low oxygen level. By this method it is possible to produce sheet that has quasi-isotropic strength characteristics, excellent toughness even at low temperatures, inclusions of favorable shape, and a low proportion of inclusions. Sheet of this grade is new in Hungary. It poses a serious task for designers of machinery and other installations, and it could provide a new impetus for designing structures of lighter weights, for the more efficient use of steel.

The ASEA-SKF ladle finishing facility to be installed in the integrated steel mill at the Lenin Metallurgical Works will provide the most modern conditions for making excellent grades of steel and alloys that have a low gas content and are highly inclusion-free.

With this equipment it will be possible to make also low-carbon steels with a carbon content of 0.03 percent maximum. This will provide, among other things, the foundation for supplying the demand for nonstabilized stainless steels used for chemical-industry equipment. The production of cryogenic steels, particularly of the 9 percent Ni grade with a low hydrogen content, could be an important contribution to equipment for the transport and storage of domestic natural gas, and also for the chemical industry.

It would be expedient to carefully weigh already now the cooperational opportunities under which the other domestic ferrous metallurgy enterprises could obtain for their own use, from LKM [Lenin Metallurgical Works], special high-grade steels or alloy components. This could be one way of substituting at least partially the import of high-grade steels from capitalist countries, the volume of which at present is about 25 million dollars. Of course, we must uncover opportunities also in other areas.

To further improve the quality of our iron and steel products, we must devote attention to influencing by modern means the crystallization of continuously cast steels. One such method, for example, is electromagnetic stirring. In our continuous casting machines, therefore, it is necessary to investigate also the feasibility of using electromagnetic stirring. Startup of a pilot plant at the Iron Industry Research Institute will be a significant step toward the domestic introduction of electroslag remelting.

It will be expedient to acquire automatic ultrasonic inspection equipment to detect internal structural defects in our products.

The ferrous metallurgy enterprises' purposeful efforts to upgrade quality will be successful if they significantly improve and develop further their relations with the enterprises that use ferrous metallurgy's products. The experience that the manufacturing plants gain in conjunction with the quality of our products must be valuable indications for technological modifications in ferrous metallurgy, in the interest of reducing the proportion of rejects. In other words, we must strive for cooperation that maximally takes into account the interests and possibilities of both sides and serves to improve the quality of the products of both ferrous metallurgy and manufacturing industry.

Further tasks in conjunction with improving quality are as follows:

The strength of structural steels must be increased, without reduction of their toughness and weldability;

The surface quality of rolled stock must be improved, and its dimensional tolerances must be narrowed;

Internal defects in forgings must be eliminated, and their allowances must be reduced;

The assortment of spheroidal graphite cast iron and of special alloyed iron and steel casting must be broadened.

We are confident that the Hungarian iron and steel workers' century-old traditional social cooperation will help us resolve also the new tasks with which we are confronted. This is cooperation within which the managing central organs, the service institutes and enterprises, and the voluntary scientific and social associations help the production plants.

The research program that serves the technical and technological development of our ferrous metallurgy can be one of the important areas of cooperation. This program dovetails without national economic objectives. Outstanding within it are the research and the license and know-how adaptation tasks that will enhance savings of energy and the improvement of quality.

A significant reduction of the specific energy consumption in the technologies of ferrous metallurgy is warranted also by the fact that ferrous metallurgy accounts for 15.2 percent of the national economy's total energy consumption.

In 1980 ferrous metallurgy's consumption of the more important fuels and electricity is expected to develop as follows:

Natural gas	$900 \cdot 10^6$ m^3 (NTP)
Oil	$200 \cdot 10^3$ tons
Coke	$2 \cdot 10^6$ tons
Electricity	2 GWh

If we include also thermal energy, the energy consumption per ton of rolled steel is of the order of 7.5 Gcal, which is 25 to 30 percent higher than the energy consumption in the countries with the most advanced metallurgical industries. In terms of saving energy, the principal directions of this R & D program are as follows:

Optimal consumption of domestic and imported coal, by modernizing the technology of coking;

In pig iron production, the introduction of technologies that reduce coke consumption;

Improvement of the energy balance in steelmaking;

Modernization of the heating furnaces at metalworking plants; and

Modernization of the annealing furnaces.

In many respects the recently completed investments and the development projects that are in progress will provide the technical conditions for improving the utility characteristics of our products, but this in itself is not enough! On the one hand we must master the expedient utilization of the new installations' technical characteristics. And on the other hand we must modernize also the metallurgical refining technology of the old steelmaking plants.

The present conference, sponsored by the Pig Iron Production Special Group and the Steelmaking Special Group within the Ferrous Metallurgy Section of the Hungarian Mining and Metallurgical Association, is proof of the voluntary technical associations' willingness to cooperate and help. The conference has placed on its agenda very important topics that directly affect the development of Hungary's iron and steel industry. I am certain that at this conference, in the same way as at the preceding conferences, our experts on pig iron production and steelmaking will be able to broaden their knowledge, to our mutual benefit, and that we will hear proposals which will facilitate the work of the central organs that manage our iron and steel industry.

SPECIALIST EVALUATES STEEL PRODUCTION

Budapest KOHASZAT in Hungarian Nos 3-4, Mar-Apr 80 pp 105-107

[Introductory address by Dr Janos Sziklavari, head of the Steelmaking Special Group, in the proceedings of the Steelmaking Section]

[Excerpt] Hungarian steelmaking can be listed at present among the leading countries only in terms of the proportion of coninuous casting. Finishing of the steel outside the furnace is limited merely to inert-gas mixing and to vacuum degassing of low effectiveness. There are no installations whatsoever for the controlled crystallization of larger ingots.

Investments in steel plants will provide for our steel industry injection equipment at Dunaujvaros, a complete ladle finishing system in Diosgyor, and additional continuous casting machines. We hope that also the steel mills in Ozd and Csepel will soon introduce the effective injection technology, and that Diosgyor will be able to build an installation suitable for the controlled crystallization of large forging ingots. The experts responsible for development will soon be able to convince themselves of the advantages of the injection technology also at home, at the Danube Iron Works; it will be unnecessary to extol this technology on this occasion. However, the same cannot be said about the technology for the controlled crystallization of large ingots! We must emphatically praise this technology also on this occasion. Not because all industrialized countries other than Hungary already have such technology (most of them employ the electroslag process), but because it can dramatically improve the quality of our forged products. Technologically a crystallizing installation can compensate for possible delays in the modernization of the forge shops, because its effect on quality is the greater.

DEVELOPMENT POSSIBILITIES AT DANUBE IRON WORKS EXPLORED

Budapest KOHASZAT in Hungarian Nos 3-4, Mar-Apr 80 pp 108-115

[Report by Dr Gellert Repasi, deputy director general of the Danube Iron Works: "Questions of Developing Pig Iron and Steel Production at the Danube Iron Works"]

[Text] Relationship between the production capacity of the sheet mills and the establishment of the new converter steel plant. Raw material and energy base for the increase of production. Supply of pig iron for steelmaking. Utilization of new technological advances in pig iron and steel production. Application of the oxygen lance in open-hearth and converter steelmaking.

Introduction

If we take also the current modernization into account, the capacity of the Danube Iron Works' wide-strip mill is 1.5 to 1.6 million tons, depending on the degree of reduction. Our plate mill is able to roll into plate about 250,000 tons of slabs. In both cases we took slabs 240 mm thick, weighing between 8 and 10 tons for the wide-strip mill. In this stage, then, the capacity of our rolling mills permits the processing of 1.75 to 1.85 million tons of slabs. These figures include also the rolling of between 200,000 and 250,000 TPY of ingots.

The capacity of both mills can be increased significantly, by continuing the modernization of the wide-strip mill, and by reducing the thickness of the slabs, respectively by increasing their weight. The rolling-mill capacities created in this manner (at DV [Danube Iron Works] and LH [Lorinc Rolling Mills] jointly) could exceed even 2.5 million tons. Here we no longer include the rolling of ingots.

The first stage represents the foreseeable future. The marketing or further processing of the products rolled from the 1.75 to 1.85 million tons of stock seems to be ensured even without significant additional investments; moreover, today this can be achieved in far more favorable variations than what we had presented in our investment proposal that was approved in 1978.

Custom processing, the volume of which is increasing even today, will fill the gap between our rolling-mill capacity and own steel output, which is still only 1.2 million tons at present. No particular explanation will be necessary to understand why it is not advantageous to load with custom processing 25 to 30 percent of a given rolling-mill capacity.

To eliminate the 500,000 to 600,000-ton shortage of stock for rolling, a converter plant with an annual capacity of 1.1 to 1.2 million tons will be built. The plant's three converters will be operated on a 2/1 basis [two in operation, one standby]. The heat size of each converter will be 130 t. Simultaneously the output of the open-hearth plant, the present capacity of which is 1.2 million tons, will be cut back to between 0.6 and 0.7 million tons. Plant capacity would permit the production of even more steel, but a prerequisite for this would be a higher increase in the output of pig iron than what has been planned.

It is understandable that the state officials in charge of managing the economy responded to the investment proposal by questioning the effectiveness of this investment. Their questions can be summed up briefly as follows: Is the material and energy base for the 0.5-million-ton increase in steel output adequately ensured, and will the expected production and sales be able to offset the substantial investment costs without any deterioration of the Danube Iron Works' present results? In my report I will attempt to prove that practical application of the recent scientific and technological advances in the production of pig iron and steel will permit the production of rolled stock that will be competitive--even when measured in terms of the world market's value judgment--and will significantly improve the economy's balance of trade. At the same time we will be able to offer domestic users several new grades of steel, and we will also be able to reduce considerably our existing import of sheet and strip.

Material and Energy Base of Increased Production

The state reports and approvals concerning the establishment of the converter steel plant determine the sources of not only the means of production but also of the quantities of materials and energy required for production. In the meantime, however, the prices of materials and fuels have continued to climb rapidly. Responding to price movements on the world market, our system of economic regulation is introducing as of 1980 certain changes in the system of producer prices. According to our computations, materials and energy will account for 85 percent of the production cost at the Danube Iron Works. These are pressing reasons to investigate whether under the altered conditions an increase in the steel output has realistic foundations that ensure economic production. We in turn formulate this question as follows: What scale of material and energy savings can ensure competitive production by the standards of the world market?

The development of energy savings to date at the Danube Iron Works is shown in Fig. 1. As evident from this diagram, the consumption of primary sources

of energy has remained essentially unchanged since 1965, even though the output has more than doubled. The quantity of purchased coking coal will increase after the commissioning of the converter plant and coking plant, but at the same time the quantity of salable energy will increase, and this will drastically reduce the indicators of specific energy consumption. On the basis of these considerations it seems realistic that we will be able to attain our objective of increasing the output of rolled steel while maintaining unchanged the net energy consumption.

Figure 1. Development of energy consumption in terms of rolled steel.

Key: 1. Rolled steel 3. Million tons
2. Specific energy consumption 4. Year

Realization of this objective is enhanced to a large extent by the fact that increase of the steel output at the Danube Iron Works can be implemented very flexibly from the viewpoint of the consumption of materials and energy. In our open-hearth plant the specific consumption of pig iron at present is 700 kg/t, and the specific consumption of scrap is 420 kg/t. These values have remained nearly constant for years, nor can they be changed significantly--for reasons we need not dwell on at present. After

the commissioning of our converters, the specific consumption of 1120 kg/t will drop below 1100 kg/t. Furthermore, the flexibility of total steel production will change considerably in terms of the composition of the charge. This flexibility is shown in Table 1, within the metallurgically feasible limits. The table confirms that the total steel output's specific scrap consumption may attain a more favorable value than at present, because our open-hearth furnaces will be transformed into scrap-melting units. Simultaneously the conditions can be ensured that will enable us to operate our converter plant at a specific scrap consumption of about 350 kg/t. On the basis of the data in the table it can be estimated that the specific scrap consumption could reach even 490 kg/t, if the national balance of scrap resources and allocations would permit such an increase. This flexibility not only allows faster adjustment to changes in the conditions of supply and demand on the world market, but it also permits the offsetting of the losses arising in conjunction with the repair of capital equipment.

Reduction of the output of open-hearth steel to approximately 600,000 tons will require the continuous operation of only three open-hearth furnaces, even if we use only solid materials in the charge and reduce the heat size to between 150 and 160 tons. One open-hearth furnace would be kept in constant reserve. But if under this mode of operation we use 350 kg of hot metal per ton, the output would increase to 800,000 tons.

If we investigate from the viewpoint of energy consumption our steelmaking system comprised of open-hearth furnaces and converters, we come to a surprising conclusion. This is evident from Table 2.

Table 1. Metallurgically Feasible Limits of Scrap and Pig Iron Consumption in Open-Hearth and Converter Steelmaking

	Open hearth	Converter	Scrap consumption Maximum	Scrap consumption Minimum
Scrap, kg/t	750	350		
Output, 1000 TPY	600	1100	835/1035*	515/1355*
	600	1400	940/1260*	590/1610*

*Consumption of pig iron

From the summary in Table 2 it is evident that the increase of steel production from 1.2 to 1.7 million tons will result in absolute savings of 171 TJ. If we take into account also the energy saved by utilizing the converter plant's flue gas, the annual savings amount to 1550 TJ. As can be seen from the table, we included the energy demand for the production of the oxygen, as well as the fuel needed to preheat the 350 to 370 kg/t of scrap to 500 °C in the converter. Considerably more energy could be saved if we were able to use waste heat for preheating.

And if we are able to achieve also our objective of increasing the output of pig iron by about 200,000 TPY at only a slight increase in the annual

coke consumption, then we may safely say that the Danube Iron Works can produce 500,000 tons more steel while maintaining the present level of its annual net energy demand.

Table 2. Development of Energy Consumption in Steelmaking

For $1176 \cdot 10^3$ tons of open-hearth steel produced in 1978:

	Tar oil	Nat. gas	Jointly	Annual consumption Tcal	(TJ)
	(Gcal/ton)				
Furnace	0.28	0.38	0.66	780	(3260)
Other	-	-	0.03	35	(146)
Jointly	0.28	0.38	0.69	815	(3406)
Fuel for oxygen production (47 m^3/t at NTP)				119*	(497)
Total energy demand of open-hearth steelmaking				934	(3904)
For $600 \cdot 10^3$ TPY of open-hearth steel, using solid charge:					
Furnace	0.30	0.80	1.10	660	(2759)
Other	-	-	0.02	14	(58)
Jointly	0.30	0.80	1.12	674	(2817)
Difference between processes				260	(1087)
For converter steelmaking ($1.1 \cdot 10^6$ TPY):					
Preheating of scrap (10 m^3/t natural gas, NTP, 350-370 kg/t preheated to 500°C)			0.08	83	(388)
Fuel for oxygen production (53 m^3/t at NTP)			0.11	126*	(526)
Other			0.02	-	
Jointly			0.21	219	(914)
Fuel saved by utilizing converters' flue gas				330	(1379)
Summary:					
Open-hearth steelmaking in 1978				934	(3904)
$600 \cdot 10^3$ open-hearth steel + $1.1 \cdot 10^6$ converter steel				893	(3721)
Savings in steelmaking				41	(171)
Savings by using converters' flue gas				330	(1379)
Total savings				371	(1550)

*0.9 kWh/m^3 at NTP; 2400 kcal/kWh

The situation is similar with respect to refractories, the other substantial cost item in steelmaking. Development of the maintenance costs of our open-hearth plant is shown in Table 3. From the data in this table it is evident that the total maintenance cost nearly doubled from 1971 to 1978, and that renovation of the brickwork and structure accounts for the bulk of the total maintenance cost. The costs of mechanical and electrical maintenance are commensurate with the increase in output and with the rise in the prices of spare parts. One of our basic objectives is to ensure that the 0.5-million-ton increase in steel output be not burdened by higher maintenance costs than what we anticipate for our open-hearth plant in 1980. Strict economy in the use of refractories is a prerequisite for achieving this objective. The attainable results are reflected in Table 4. As can be seen from this table, our consumption of every type of refractory material will decline, despite the 0.5-million-ton increase in steel output. Realization of this objective, however, presupposes the following:

The quality of the employed, mostly basic, refractory materials will conform to the modern level, regardless of whether these materials are domestic-made or imported;

The time available for relining will result in a significant improvement in the quality of relining;

The latest results of scientific research into the metallurgical processes, primarily into curbing slag-caused corrosion, will be applied in practice;

Our output of ingots will not increase above the 1979 level.

(8) Átlagos adagsúly t	256,8	187,2	175,6	147,4	93,9	245,3	151,3	271	110,5

Key:
1. Converters Nos 1-9
2. Service life of lining (heats)
3. Consumption of working lining, kg/t
4. Consumption of rammed material, kg/t
5. Consumption of safety lining, kg/t
6. Consumption of patching materials, kg/t
7. Relining time, hours
8. Average heat size, tons

To insure the realization of these objectives, in our open-hearth plant the heat size will be reduced by 15 to 20 tons; and the quantity of slab, by 60 to 70 percent; furthermore, no oxygen will be added, and one open-hearth furnace will serve as constant standby capacity. As proof that the consumption of refractories planned for our converter plant is realistic, we offer a comparison of the data for the nine converters that operate at a modern level (see Table 5). This table reflects the changes in the quality of refractories, the spreading use of the slurry-spraying technology, and also the present level in the mechanization of relining. The data in Tables 3 and 4 justify our expectation that the maintenance cost of steelmaking will remain at the present level despite the startup of the converter plant, and also that we need not anticipate any increase in manpower requirement for maintenance, materials handling, storage and stockpiling.

The situation is not so favorable with respect to the consumption of alloying materials. Total consumption of alloying materials in our open-hearth plant in 1978 was 20,150 tons or 17.1 kg/t. This high specific consumption reflects the large proportion of low-alloy products within the output (plate and tubing of high purity), and it also calls attention to the task of finding new ways to reduce the loss of alloying materials due to burning.

The distribution according to types of alloying materials used is as follows: FeMn, 9.5 kg/t; FeSi, 2.5 kg/t; Al, 1.1 kg/t; FeSiMn, 2.5 kg/t; and the balance consists of alloying materials containing V, Nb and rare-earth metals. Even today a proportion of the consumption is supplied through import from capitalist countries, and the FeMn, CaSi, FeSiMn, V, Nb, FeCr and Ni needed for the increase in output can be procured only from capitalist countries. However, the cost impact of this import can be reduced through new metallurgical methods that aim to drastically curtail the slag-induced oxidation losses.

In recent months the outlines have begun to emerge of the feasibility of supplying the increased FeMn demand by reducing our Mn oxide ores. The ladle-finishing processes will increase the consumption of Ca-Si and other complex alloying materials, but at the same time it will be necessary to crush these alloying materials and to produce specified grain fractions.

The production of such fractions is ensured by the fact that we will solve the crushing, grading, storage and conveyor-belt handling of the alloying materials simultaneously with the construction of our converter plant.

Development in the direction of exporting more-valuable products would require that we export also alloyed sheet. But if the alloying materials for this purpose can be obtained only through import from capitalist countries, the economic effectiveness of such export might become questionable. Therefore we must continue to seek possible ways of producing alloying materials based on domestic raw materials or on socialist integration.

Supply of Pig Iron for Steelmaking

Ironmaking experts are fully aware that the technical-economic indicators of pig iron production lag significantly behind the values that are now feasible. The extent of this lag is best illustrated also at the Danube Iron Works by a difference of 200 to 25o kg/t in the specific coke consumption.

In conjunction with supplying pig iron for the converter plants under construction, this question has been emphasized in recent years in studies and reports, before several forums.

It is also true, however, that the processes and methods already elaborated for developing the technology of ore preparation and pig iron production would have to be introduced--after adapting them to our natural conditions--even if, for example, we did not want to increase our output of pig iron. Profound economic analyses are unnecessary to perceive what benefits our economy could derive from such advantages as the significant savings of energy, the rapid rise of labor productivity, the lower costs of protecting the working and natural environments, etc.

To illustrate: We are familiar with the data of the 1000 m^3 blast furnace in Cherepovets, and we know that its annual output is slightly more than the combined annual output of the two 960-m^3 blast furnaces at the Danube Iron Works.

The geographic location of the Danube Iron Works places it in a favorable position to produce pig iron that can be competitive even on the world market. Thanks to the proximity of the Mecsek coal basin, and to the feasibility of transporting by water its substantial coal reserves and the iron ore, the Danube Iron Works would be able to produce pig iron at lower cost than the other iron works in its vicinity, even if the energy costs were identical. We have already taken several steps toward becoming competitive, but even so our lag is still significant. The concluded Hungarian-Soviet intergovernmental agreement for the supply of an agglomerating plant, and the technological investments in conjunction with the construction of the converter plant already represent significant progress. We demonstrate this in terms of the technical-economic indicators in Table 6, projecting also the future possibilities. Aside from the 200,000-ton increase in pig iron production, progress is evident in that the additional coke required for this purpose is barely 30,000 TPY. Technological progress manifests itself essentially in a drastic reduction of the agglomerate's dust content, in the better-grade coke that can be obtained simultaneously with the coking plant's modernization, in the increase of the blast temperature by 100 to 150°C, and in the moderate increase of the top pressure and the blast's oxygen enrichment. Even so we will have to melt 780 kg of slag per ton. This situation will ensure fulfillment of the steelmaking targets set for the Sixth Five-Year Plan.

6. With new agglomerating plant
7. With improved charge

The coke demand of pig iron production (Table 7) could be covered even from our present coke output. The coking plant to be built with a capacity of 1.0 million tons will add about 300,000 TPY to the supply of domestic demand for coke, primarily for our sister plants. The dry coking technology that will be installed in the new coking plant will further reduce the absolute energy demand by 40 tons of steam per hour.

In the interval between the completion of the new agglomerating plant and the running-in period of the converter plant we intend to insure the burden ratios by increasing the proportion of scrap.

Our ironmaking experts have estimated the improved technical indicators that can be achieved through the further adaptation of the results of developing our pig iron production. These indicators are presented in the third column of Table 6. They represent the economic advantages that can be attained through the successful conclusion of the Hungarian-Soviet negotiations for the procurement of iron-rich ores or enriched ores. The economic advantages will be apparent predominantly in a reduction of the specific coke consumption to between 450 and 460 kg/t, while at the same time the output of pig iron could reach 1.5 million tons. The coking plant to be built will still be able to amply supply the 675,000 to 690,000 tons of coke per year required for this output. In this case, at an increase of barely 100,000 tons in coke consumption, the annual output of pig iron can be increased by 450,000 tons. The supply of coal to produce 1.0 million tons of coke per year will still not require the opening of new mines, provided we can maintain at the present level the import of coal from socialist countries. By introducing the practice of preheating the coke, also the domestic base of coking coal can be expanded, and the coke output can be increased to 1.3 million tons. If sufficient coal is available, one of the shut-down coking batteries could perhaps be reactivated.

However, the third column of Table 6 does not yet reflect the complete adaptation of our development results to date. A burden yield of 58 to 60 percent, a blast temperature of 1300°C, and the injection of 200 m^3 of natural gas per ton (at NTP) represent considerable progress. But still unutilized is the effect of such essential technological changes as ore averaging, screening out before the top the ore particles less than 5 mm in size, increasing the top pressure to between 1.8 and 2.5 atm, computerized process control, and also the results of R & D now underway. One such result, automatic measurement and control of the coke's moisture content, could find practical application in the near future. However, we must reckon also with the fact that the increased output will require simultaneous modernization of the materials handling and charging systems.

Utilizing Scientific and Technological Advances in Developing the Production of Pig Iron and Steel at the Danube Iron Works

In the following I wish to dwell on the utilization of the advances in science and technology, because I am convinced that in this way we are

able to supplement our lacking material and energy resources at the lowest outlays but with the greatest economic effectiveness.

In the area of ore preparation, for example, the quality characteristics of the agglomerate from the agglomerating plant to be built will change as shown in Table 8. The 5 percent maximum proportion of ore particles less than 5 mm in size, and the disappearance of 250-mm ore lumps will represent great progress in comparison with our present situation, and this will be further enhanced by the advantages of charging at ambient temperature. These changes are due to the application of two-layer charging, heat-treatment-like cooling of the agglomerate, double screening and methods of cooling. Further possibilities lie in using larger quantities of quick-lime --this will be made possible by the lime kiln to be built for this purpose-- and in narrowing the variations in the chemical composition of the aggregate by ore averaging. It would be a great advantage if the Hungarian-Soviet negotiations lead not to the production of Krivoy Rog concentrate but to the feasibility of using rich agglomeration ores. Such an agreement would not reduce the production capacity of our agglomerating plants, but our domestic investment costs would be lower. The energy efficiency of these changes will be enhanced by the advantages arising from the quality of the coke (Table 9), and particularly from a favorable reduction of the coke sizes. We regard the 12.5 to 13.5 percent ash content, and the 1.5 percent S content as additional metallurgical costs resulting from our reserves of coking coal. However, this should not hamper utilization of our reserves of coking coal, because the by-products of washing the coal, for the purpose of reducing its ash content, can be used efficiently to generate electricity, and the harmful effects of the approximately 1.5 percent S content can be offset by already known metallurgical methods. And the sulfur extracted from the coke gases provides a way to supply our demand for sulfuric acid.

It is a known fact that the effectiveness of technological changes to increase the production rate of the blast furnaces is closely related to the quantity of slag that has to be melted. Most technological changes are the more effective, the less slag there is to melt. From 1978 through 1981 we will be investing about 650 million forints to develop our technology for the production of pig iron. This includes 350 million forints for investments related to the converter plant. With the commissioning of a new turbo-blower plant we will ensure the conditions for employing a top presssure of 1.5 atm also in our No 1 blast furnace. Reconstruction of the heating stoves will enable us to raise the blast temperature to 1250°C, even though the selected solution--i.e., the use of heating stoves with external shafts--is still not the most modern one. Our unfavorable burden ratios compelled us to make this compromise. A further great step ahead is the oxygen-enrichment of the blast to an oxygen content of 30 to 32 percent. We have already introduced evaporative cooling in one of our blast

Table 9. Quality Indicators of Metallurgical Coke

furnaces, with significant savings of energy. Redesigned tuyeres--with a service life several times longer than that of the present ones-will be installed in the near future, on the basis of a Sovet license. To increase the frequency of tapping and to lengthen the service life of the tapholes and runners, it will be necessary to use new refractory materials. We know of runner-ramming compounds that permit the tapping of even more than 100,000 tons of hot metal. At the same time also the tedious work of chipping the runner lining will be mechanized. We have prepared plans to use the blast-furnace slag for road construction, and to recover the Fe and refractory materials from the slag dumps.

Steelmaking by the converter process stipulates well-known quality requirements regarding the chemical composition of the hot metal and its temperature. Certain computations lead us to the conclusion that we must anticipate the need to increase the temperature of the hot metal, which will be accompanied by a slight increase of its Mn content. Because of energy considerations, only practice can provide the right answer to this question. We believe that construction of a 1300-ton mixer ensures the requirements of steelmaking with regard to uniform chemical composition.

In view of the specific coke consumption's planned reduction--and also because the processes for desulfurizing pig iron are expensive and involve heat losses--we are not planning to introduce a new desulfurization process. This is warranted by the fact that ladle finishing already provides a process for the desulfurization of steel.

Our results to date in developing the technology of steelmaking have been significant. The more-important stages in the development of open-hearth steelmaking are as follows: increase of the bath surface (charge weight); modernization of furnace design, and of the methods of building and repairing them; use of refractory materials of excellent quality; introduction of slurry spraying to repair the furnaces; oxygen injection; lining the ladles by ramming instead of with brickwork; modernization of the preparation and charging of the scrap; and constant improvement of our metallurgical methods. The present, nearly 1.2-million-ton output of our four open-hearth furnaces, originally with a heat size of 125 tons each, and the pertinent assortment of steel grades reflect to some extent the magnitude of these efforts. Most of the workers, technicians and engineers who are helping to raise the level of our steelmaking will be somewhat saddened by our having to outline a less spectacular future for open-hearth steelmaking. This future can be spectacular not in terms of tonnage, rather in the improvement of economic effectiveness and quality. The open-hearth plant will be modified to melt scrap, and it will change over mostly to the production of high-strength plate and of starting materials for the production of tubing.

The new possibilities for rapidly altering the oxygen activity and basicity of the reduced volume of slag have provided already realistic and economic ways to introduce new alloying processes, particularly if we combine them with the methods of ladle finishing.

The most significant, and economically the most successful, technological investment at the Danube Iron Works in years past was the construction of continuous casting units. An intergovernmental agreement ensures the construction of also a third continuous casting unit.

We nevertheless are planning to modernize also our existing casting plant. Built originally for a capacity of 800,000 TPY, the present output of the two-strand continuous casting unit of the vertical type already exceeds 950,000 TPY, and the quality of the sheet rolled from the continuously cast slabs is superior to that of the sheet rolled from ingots. The experts of Gipromez [State All-Union Institute for the Planning of Metallurgical Plants] designed the planned modernization. Its essence is a turntable mounted on the vertical casting machines' steel structure, permitting an increase in the proportion of strands cast from heat to heat. The geometric shape of the tundish has been redesigned. The relatively large tundish offers metallurgical advantages as well, in that it has also provisions for retaining the slag. Application of the new types of refractory materials developed for the brickwork and lining of the ladles, and for lengthening the service life of the tapholes and plugs, has drastically reduced the downtime, increased the output and curtailed the quality defects resulting from the refractory materials. Expedient division of the production program between the open-hearth and L-D plants also makes feasible the series casting of heats of identical quality.

These conditions, we believe, ensure that the increase in the steel output will manifest itself not in ingots but in continuously cast slabs.

Modernization of our continuous casting units does not make superfluous the construction of a third, curved-type continuous casting unit. To the contrary, not only will the construction of this third unit permit the complete discontinuation of ingot teeming and the dismantling of the soaking pits that have been written off long ago, but also reduction of the gage of the slabs to between 180 and 200 mm will increase the output of our reversing slabbing mill and plate mill.

In the meantime the individual elements of the system for controlling continuous casting have already been developed. Such elements are, for example, automatic level control in the crystallizer, control of cooling, automatic cutting of the strands, and control of the process of crystallization through electromagnetic stirring. However, the other elements for complete automation are still lacking. One of the most difficult tasks appears to be control of cooling at such degree of automation that always ensures the same surface temperature along a given cross section. Automatic coordination of the isotopic pool-gage readings with the pouring rate could speed up pouring. Complete automation of continuous casting is within our reach.

The metallurgists and refractory experts at the Danube Iron Works have made no small contribution to the development to date. For cast slabs to be

rolled into sheet, they developed a deoxidizing method that can avoid surface defects due to blisters or to Al_2O_3 nodules. These slabs need not be stripped before they are placed in the pusher-type furnace. Similarly successful was the research into optimizing the deoxidation of high-strength starting materials for tubing. The attained results are relected in the following technical characteristics: Tubing made from cast billets without stripping meet the API specifications with 95 percent certainty, and the specific consumption of steel is 1180 kg of continuously cast billets per ton of tubing. In the course of this research we clarified the metallurgical and technical conditions of the formation of globular oxide inclusions, and of avoiding sulfite II-type inclusions. We likewise clarified the effect that the reactions taking place at the liquid-crystal interface have upon the morphology and arrangement of the inclusions arising during crystallization.

Our refractory experts have made great strides toward the exploitation of our domestic mineral resources and the application of new types of refractory materials. One of the greatest potentials for developing our production of pig iron and steel lies in the fastest possible utilization of the results achieved in improving the quality of the refractories and in the technology of their application. From the literature we know not only of refractory compounds that withstand the teeming of 100,000 tons of hot metal, but also of converter linings that withstand several thousand heats, and of ladles that withstand 40 to 50 heats.

If we solve these tasks with the wider participation of our domestic resources than up to now, we will be able to report further economic results. However, we will not be able to dispense even in the future with the systematic monitoring and application of the results achieved abroad.

Outstanding among the measures now underway or being planned to improve the quality of our sheets are the possibilities of deoxidizing, desulfurizing and alloying steels by the method of ladle finishing. The license and know-how that the KCM [Ministry of Metallurgy and Engineering] purchased with the assistance of OMFB [National Technical Development Commission] will find full-scale application already this year. The process will cause a sharp rise in the quality of our plate and tube steels, because it is able to reduce the S content of the steels even below 0.005 percent; and their oxygen content, below 0.002 percent. Elimination of II-type inclusions, and the formation of globular inclusions as a result of their Ca content, will permit the production of plates and tubing that have spatial isotropy. The impact strength values change within a temperature range of +20°C to -60°C as shown in Fig. 2.

Figure 2. Transverse impact strength.

Key:

1. With injection
2. Without injection

We expect similar results also in the improvement of sheet quality, although we have not yet tested the process for this purpose. We believe that the experiments to be conducted in October and November will confirm our expectation that continuous casting of heats containing less than 0.01 percent S to avoid fissuring of the cast strand, and the reduction of the oxygen content below 0.01 percent will result in an improvement of the surface quality and of the ductility characteristics (Erichsen, $\bar{r}$ and $\bar{n}$). An increase of the steel's Ca content will facilitate the continuous casting of steels containing Al, because there is less danger of shell shrinkage caused by the Al_2O_3 and therefore casting can proceed at a faster rate and more evenly.

In conjunction with the introduction of this process--as one of its preparatory stages--we developed a method for retaining the open-hearth slag in the furnace, and for treating with synthetic slag the small amount of slag remaining on the surface of the molten steel in the ladle. By this method the oxygen activity of the open-hearth slag can be drastically reduced, and its basicity can be modified. The results of one such experiment are presented in Table 10. Reduction of the oxide content to about 6 percent FeO not only provides favorable conditions for desulfurization but also lengthens significantly the service life of the ladle lining and reduces the specific consumption of alloying materials that have a great affinity for oxygen. By this method it is possible to achieve 30 to 40 percent desulfurization during tapping. Therefore we wish to use this method intensively in our open-hearth plant as well as in our converter plant.

Table 10. Treatment of Open-Hearth Slags by Ladle Finishing

5. After argon flushing

Even on the basis of what has been said up to now we may answer with confidence the question raised in the introduction. The answer is that an increase in the output of pig iron and steel at the Danube Iron Works is a worthwhile undertaking even by the standards of the world market. It will contribute toward increasing our national income, as well as toward improving our balance of trade. One of the principal guaranties of achieving these results is that we will employ the latest advances in engineering and technology, adding to them the fruits of our own research and development while also seeking assistance from the brainpower of the domestic institutions and research institutes concerned with research and development.

DEVELOPMENT POSSIBILITIES AT OZD VIEWED

Budapest KOHASZAT in Hungarian Nos 3-4, Mar-Apr 80 pp 115-118

[Report by Dr Emil Furjes, metallurgical engineer and department head at the Ministry of Metallurgy and Engineering: "The Problems of Developing the Production of Pig Iron and Steel at the Ozd Metallurgical Works"]

[Text] Evaluation of the present state of pig iron production. Developmental possibilities: lengthening the service life of the blast furnaces' lining and improving the burden yield, by reducing the dust content of the agglomerate and the basicity of the slag. Increase of the blast temperature. Development of steel production, by improving the supply of scrap and alloying materials. Introduction of ladle finishing in the pouring bay, to produce high-grade s eel.

The blast furnaces at OKU [Ozd Metallurgical Works] were built in the 1950's, and the steel plant assumed the main features of its present aspect in the mid-1960's.

Already in the second and third year after their reconstruction, the modernized metallurgical plants produced substantially more than had been planned, and they also had favorable conditions for the adoption of further organizational and technical measures, and for the expansion of production. Whereas in 1968 we produced 514,000 tons of pig iron and 800,000 tons of steel, our targets in the 1979 plan call for 960,000 tons of pig iron and 1.4 million tons of steel. On average over the ten years, then, our annual growth rate exceeds 8 percent, which is noteworthy in metallurgy.

Pig Iron Production

Pig iron production at the Ozd Metallurgical Works at present is characterized by the following more important technical indicators (see Table 1).

Table 1. Some Technical Characteristics of the Blast Furnaces at the Ozd Metallurgical Works

Approximate service life of blast furnace, years	6
Burden yield, percent	42
Blast temperature, °C	900
Coke consumption, kg/t	690
Natural gas consumption, m^3/t at NTP	70
Production rate, tons of charge/m^3 and day of operation	2.9
Coke rate at tuyere level, kg of coke/m^2 and hour of operation	720
Annual output of pig iron, 1000 tons	900
Working volume, m^3	2300
BEM [Borsod Ore Dressing Plant] Fe content, percent	46
BEM basicity	0.99
BEM dust content, particles less than 0.5 mm, percent	16
Basicity of slag	1.23

Examination of these indicators enables one to draw several essential conclusions. Let us examine one by one the most important indicators from which we can draw conclusions decisive for the future.

The service life of a blast furnace is 6 years! This is in agreement with the domestic average, but we should know that countries more developed than ours have attained a service life as high as 10 to 12 years. Since the relining of a blast furnace takes 100 to 120 days, lengthening the cycle is a significant factor in the better utilization of operating time.

I do not wish to discuss in detail the significance of improving the utilization of operating time, but I would like to emphasize the Hungarian metallurgy also must devote more attention to this question, because this is warranted by numerous technological, economic and technical factors.

Longer service life is influenced, among other things, by a suitable jacket, effective and reliable shaft-cooling systems, fuel of better quality, and more-efficient modes of operation, all of which can be ensured only through purposeful development activity.

According to the experience of the Ozd Metallurgical Works, use of a carbon compound for ramming the bottom has proved suitable, and we believe that at the next relining it will be possible to retain the bottom for another campaign. The situation with regard to the jacket and cooling system, however, is unfavorable.

We used a vertical cooling-plate system for the first time in 1973, when the No IV blast furnace was relined. On the basis of the designer's favorable opinion, we successively installed this cooling system in the other blast furnaces as well. But it turned out that the cooling plates were of unsuitable design, burned out soon, and it was practically impossible to repair them. Leaks ruined the brickwork ahead of time, peeling of

the accretion became more frequent, and the number of tuyeres that had to be replaced nearly doubled.

The burden yield is 42 percent! This value is the lowest even for Hungary. The question arises as to what causes this. The answer can be formulated as follows:

The Fe content of the BEM concentrate that constitutes the bulk of the charge is 2 to 3 percentage points lower than the Fe content of the agglomerate produced at DV [Danube Iron Works]; this is related to the distribution of the concentrate.

The charge contains less of so-called shaving iron than at LKM [Lenin Metallurgical Works].

The basicity of the blast-furnace slag at the Ozd Metallurgical Works is unjustifiably high, 1.23; at an SiO_2 content of 15 percent or more in the agglomerate, this means that nearly 900 kg slag is formed per ton of pig iron.

From the professional literature and foreign experience we know that today many countries operate with a burden yield of 55 percent or more. Experts likewise know that improvement of the burden yield is a worldwide trend. Efforts are being made in this direction also within Hungarian metallurgy, by modifying the international agreements and with the help of development measures. However, these efforts will mature only by the end of the Sixth Five-Year Plan at best, and until then the composition of the charge will not change significantly.

Thus our possibility and task is to achieve improvement under the present burden ratios. In my opinion, the burden yield could be increased by 3 or 4 percentage points with the help of the following measures:

The quality of the agglomerate should vary as little as possible in terms of its basicity, and of its Fe, SiO_2 and dust content, so that the conditions for even operation of the blast furnaces may improve.

To this end the following are necessary:

Better averaging of ores and solid fuels;
Sizing of the agglomerate;
Reasonable reduction of the flux in the charge, in the interest of maintaining the basicity between 1.1 and 1.15.

Of the partial measures our enterprise is perhaps best able to influence this last requirement, whereas the other measures require the coordinated activity of two or three enterprises. I am convinced that we will avail ourselves of these opportunities in the near future, for the interests of both the national economy and the enterprise increasingly point in this

direction. If, for example, the basicity were reduced to 1.15, the burden yield would increase by about 2 to 3 percentage points, as a result of which our output of pig iron would increase by 40,000 to 50,000 TPY, respectively we could save between 25,000 and 30,000 tons of coke a year. However, the sulfur content of the pig iron must be reduced by desulfurization outside the blast furnace.

The blast temperature is 900°C. This indicator does not rate as good even by domestic standards, not to mention the leading foreign countries where blast temperatures of 1300°C are already being used. The effects of increasing the blast temperature, and also the prerequisites for this, are well known. To attain a higher blast temperature we need, among other things, a suitable set of heating stoves, a system of blast mains and connections (from the heating stoves to the tuyeres) that operate reliably even at high temperatures, and a permeable charge that permits larger volumes of gases to move through the column.

None of these conditions can be met at the Ozd Metallurgical Works at present.

The capacity of the set of heating stoves is inadequate, and the rate at which they are being rebuilt is insufficient even to maintain the results already achieved, not to mention further development. Our system of blast mains and connections is unsuitable even for a blast temperature of 1000°C. The high dust content of the BEM agglomerate, in combination with the varying tumbler-test strength of coke, practically excludes the application of the mentioned blast temperature.

An action plan sums up what has to be done and includes, among other things, the following:

Rapid reconstruction of the existing heating stoves, including reconstruction of the base and relining;
Reconstruction of the No 13 stove;
Installation of ceramic burners and modern dampers, and modification of the gas and air mains;
Construction of a new smokestack, and reconstruction of the two existing smokestacks and flues;
Construction of two new heating stoves (Nos 14 and 15);
Relining of the hot-blast mains, using special insulation.
Development of our hot-blast auxiliaries can be effective only if the dust content of the balst-furnace gas used to heat the stoves is reduced to at least 15 mg/m^3 at NTP. This will be ensured by the operation of the proposed two new electric precipitators (Nos 5 and 6), and by improving the efficiency of the existing ones.

The coke consumption is 690 kg per ton of pig iron, which is worse than the specific coke consumption at the Danube Iron Works or Lenin Metallurgical

Works. The international level is around 500 kg/t, but the most advanced blast furnaces attain a coke consumption of less than 400 kg/t.

It follows from even this brief comparison that our tasks from the viewpoint of both technology and economic effectiveness are becoming more and more urgent.

The already mentioned three factors--service life of the blast furnace, burden yield and blast temperature--are correlated with coke consumption. Confirming and supplementing what has been said above, I wish to outline our possibilities as follows:

First and foremost, we must ensure even operation of our blast furnaces. The most important factors that affect even operation are: the charge; the level of maintenance work; and the turnover, materials handling and management of operations.

In our previous discussion of the charge I have not dwelt on one important area, the state of the stockyard.

The charging system of the stockyard is obsolete and unreliable, with regard to both coke and ore, because the scales are off. The coke is now being measured by volume, and its weight is being calculated theoretically.

In recent years we had SZIKKTI [Central Research and Planning Institute of the Silicate Industry] prepare a preliminary plan for modernizing the charging system.

Under the Sixth Five-Year Plan we are planning modernization at two blast furnaces, with outside support.

Among the maintenance tasks I would like to call attention particularly to the following:

Systematic inspection of the blast furnaces' cooling systems, and immediate prevention of breakdowns;
Systematic repair of the heating stoves, air mains and their fittings, in order to reduce air, gas and heat losses;

Closer attention must be devoted than up to now to the planned maintenance of the heating stoves. We must avoid having a stove out of commission for more than a quarter at a time, while it is being relined.

The on-schedule transportation of the raw materials for the charge is generally solved, except under exceptional traffic conditions (for example, during floods, snowstorms, and shortages of coke). The same cannot be said about materials handling at the plant, primarily about the supply of slag cars.

The main cause of this situation is the periodic severe shortage of freight cars, and the overfilling of the slag dump. Therefore the transportation or disposal of the slag is one of our key tasks. The pertinent plans have already been worked out, and the most important provision in them is the establishment of a new slag-dumping area at Center.

To sum up the present evaluation of the blast furnaces at the Ozd Metallurgical Works, I regard the following as a guide to the limitations on, and the indications of, our future tasks:

1. The addition of new blast-furnace capacity cannot come into consideration, but better utilization of existing capacity is and will be necessary, from the viewpoint of both production volume and economic efficiency. The possibilities for this do exist: improvement of the quality of the charge, oxygen enrichment, and increase of the top pressure are the best-known possibilities for intensification.

2. Among our future tasks, emphasis will be primarily on producing pig iron of better quality at low cost, and not on increasing the output. The prerequisites for this are a reduction of the specific coke consumption, and improvement of the conditions that influence this consumption. The factors that affect the specific coke consumption warrant close cooperation among the metallurgical enterprises on adopting technical and operational measures that will serve to improve the quality of the charge. This circle of tasks includes the development of tuyere designs, cooling systems and charge preparation, improvement of the operation of the heating stoves, oxygen enrichment of the blast, and many other measures. To the best of their knowledge, the metallurgical enterprises have started off in the right direction, and I am confident that their cooperation will produce the desired results in the near future.

3. The development of maintenance, more-efficient organization, and the use of credit resources for energy savings may be regarded as reliable ways of attaining better technical indicators. Other resources for investments can hardly be expected, in view of what expenditures the national economy is able to absorb.

Steelmaking

As I have already mentioned, we completely rebuilt our open-hearth plant under the reconstruction program that ended in the mid-1960's. Since then the heat size of our furnaces has increased from 80 tons to 110 tons, and in the autumn of 1977 the construction of a 10,000 m^3/hour (NTP) oxygen plant enabled us to increase the oxygen consumption from the 10 to 11 m^3/t (NTP) earlier, to 40 m^3/t (NTP). Parallel with the construction of the oxygen plant we enlarged the charging auxiliaries of these furnaces, and the auxiliaries of the pouring bay. One of our most significant investments has been a modern, six-strand, curved crystallizer-equipped continuous casting machine built under a Concast licence. We placed this

unit in operation in the autumn of 1973, and its present output is 330,000 to 340,000 tons of 120 by 120 cast billets.

Some technical characteristics of our steel plant are presented in Table 2.

Table 2. Some Technical Characteristics of the Steel Plant at the Ozd Metallurgical Works.

Bath surface of furnace, m^2	40
Steel output, 1000 TPY	1360
Furnace production rate, t/hour	20
Average heat load of furnace, GJ/hour	70
(Gcal/hour	16.6)
Specific heat consumption, GJ/t	3.65
(Gcal/t	0.87)
Specific oxygen consumption, m^3/t	40
Average yield, t/heat	106
Metallic charge, kg/t	1154
Metallic charge and added ore as 100 percent Fe, kg/t	1165
Duration of campaign (number of heats)	355
Blowing-out, percent	8.8
Damping-down, percent	2.2
Utilization of operating time, percent	89
Rejects, percent	0.9
Proportion of pig iron in the metallic charge, percent	60
Total refining material added, kg/t	43

On the basis of the data in the table, we may establish the following:

For the given bath surface, heat load, oxygen enrichment, charge ratios and operating conditions, most of the technical indicators may be judged good, by both domestic and international standards. This applies primarily to the utilization of operating time, to the tons/hour production rate and to the proportion of rejects, but also the other indicators tolerate the test of comparisons. The production rate of the open-hearth furnaces is significantly lower than that of modern steelmaking installations (L-D, QuBOP, UHP Electro); for example, it is about one-fifth of the production rate of a converter of the same size.

In my opinion, the value of the specific metallic charge is acceptable. In the area of charging and the technology of process control, however, the efforts to further reduce the value of this indicator must be continued. Accurate weighing can narrow the variations of yield and reduce the losses of steel during tapping. Further perfection of the technology of process control can reduce losses of metal mixed and removed with the slag. Because losses of metal in the slag are significant, I will dwell on this question in somewhat greater detail.

The Fe content of the slag during meltdown with oxygen injection can be as high as 30 to 40 percent. According to our earlier technology, we tried to remove the slag from the furnace as early as possible, partially for quality considerations and partially to shorten the charge-to-tap time.

Early slag removal, however, had also a negative effect: The specific metallic charge, in terms of Fe, reached a value of 1185 kg/t, and this would have resulted in a loss of about 120 million forints a year had we not taken appropriate action in due time. The essence of our measures can be summed up as follows:

The hot metal must be added to the furnace not later than 35 minutes after the completion of charging, and process control (heating, injection of oxygen) must be directed so that the flushing of the slag from the furnace is delayed, occurring 20 to 30 minutes after the addition of the hot metal. By this method we avoided an increase in the charge-to-tap time and reduced the metallic charge by about 20 kg/t.

Similar possibilities exist for introducing optimal firing, to reduce the specific calorie demand.

As can be established from what has been said above, the main problems of our steel plant concern not the furnaces as the principal production installations, but primarily the pouring bay. Here the present practice of preparing the ladle and molds causes problems. The steel ladles are lined and dried mostly by conventional methods. Applying the refractory mortar with a pneumatic gun could eliminate heavy physical labor, and at the same time the service life and safety of the ladle lining would be improved.

The use of hot tops could simplify the manual operation of preparing the molds, and this would also influence favorably the reduction of frothing losses.

The method of adding alloying materials likewise must be changed urgently, with special attention to the considerations of quality improvement, and savings of manpower and material.

Haphazard supply of scrap and refractory materials for the open-hearth furnaces is causing much confusion and considerable difficulties. Progress is not fast enough in the wider use of domestic refractories, for the substitution of imported brick.

In summing up the most important tasks of steelmaking at the Ozd Metallurgical Works, I wish to emphasize economic effectiveness, quality and the elimination of heavy physical labor. Very likely the Ozd Metallurgical Works will not have to produce more than 1.4 million tons of steel, but the technical parameters and the quality of the produced steel must be improved. The tasks follow from the outlined state of the furnaces and auxiliaries. Improvement of the production conditions and the attainment of new results

must be accelerated not through large-scale investments, but through upgrading and modernizing investments and through maintenance. Among the measures to improve quality we may consider also the extension of new technologies.

Colleague Sziklavari mentioned the advantages and potential applications of ladle finishing. In agreement with him, I would like to call special attention to lance injection. In the future we will have to devote ever-greater attention to improving the working conditions and also to the replacement of manpower, because at the Ozd Metallurgical Works there are perceptible problems also in this area.

I am convinced that the managements of the enterprise and of the factory unit will adopt the most effective measures possible, and that the sister enterprises, the Ministry of Metallurgy and Engineering and the other national organs will render maximum assistance. Within a few years these joint efforts will certainly be reflected also in the results.

DEVELOPMENT AT LENIN METALLURGICAL WORKS DISCUSSED

Budapest KOHASZAT in Hungarian Nos 3-4, Mar-Apr 80 pp 119-123

[Report by Rezso Herendi, metallurgical engineer and technical director of Lenin Metallurgical Works: "The Questions of Developing Iron and Steel Production at the Lenin Metallurgical Works"]

[Text] Description of the blast-furnace plant and of its production results. Summary of the production installations and achieved results of the present open-hearth steel plant and electric steel plant. Establishment of a new integrated steel plant. The two phases of building the new steel plant: an 80-ton UHP electric furnace and continuous casting machine. Preparations for the start-up of the new plant.

The blast-furnace and steelmaking installations at the Lenin Metallurgical Works cannot be regarded as modern installations.

In terms of age, size, design and auxiliaries, our blast furnaces lag far behind the now customary and technically expected level. The open-hearth process already is regarded as obsolete, and our open-hearth plant is uneconomic, obsolete and hazardous. Among our electric furnaces there are also units that are still charged manually, and only the 50-ton Soviet furnace meets modern requirements.

With such equipment we cannot achieve our objective of modernizing our products and making them more economic. In January 1977, therefore, investment decisions were made at the cabinet level that call for the establishment of a modern steelmaking base.

Our pig iron production, too, must keep pace with the quantitative and qualitative development of steel production, and with the efforts to make it economically effective. At the Lenin Metallurgical Works the output of pig iron is nearly double the output of ten years ago. This development was achieved not by building new blast furnaces or expanding the existing ones, but by improving the level of charge preparation and by introducing various technological methods.

As a result, the specific coke consumption dropped from 840 kg/t in 1968, to well below 700 kg/t at the beginning of 1970. Of course, the injection of natural gas and the increase of the blast temperature were contributing factors in this.

Gradual improvement of the pig iron's quality and of the uniformity of its chemical composition kept pace with this quantitative growth.

Concerning the improvement of quality, special mention must be made of the uniformity of the chemical composition, particularly of the extent of variation in the Si and S contents. According to our data on the frequency distribution of the Si content, the proportion of output whose Si content exceeded the ±0.1 percent range of variation from the average dropped from 75.1 percent in 1968 to 39.7 percent in recent years. The same trend can be observed in the frequency distribution of the S content.

Aside from the worn-out state of the No III blast furnace, our present output of pig iron satisfies the quantitative and qualitative demand of our open-hearth steel plant.

With the startup of the converter steel plant, we must increase the output and significantly improve the quality of the pig iron, because its composition--specifically the actual Si, S and Mn content and their minimal variation--is an important factor in the utilization of converter capacity. Because of financial constraints, only partial measures are feasible, and we are able to ensure merely conservation of the Nos I and II blast furnaces, of their brickwork, stoves and other auxiliaries.

The No I blast furnace was rebuilt in 1978, without a new jacket after five years of operation. In the course of this we also reinforced the steel structure of the skip bridge. In view of the blast furnace's five-year campaign, we did not anticipate significant wear of the hearth's brickwork, and therefore we blew the blast furnace down without tapping the bottom. After blowdown and scraping out the bottom, however, we found so extensive erosion that the hearth lining had to be replaced. Because of this, reconstruction of the blast furnace took 39 days, instead of the 25 days planned.

We rebuilt the No II blast furnace this year, in 45 days instead of the 60 days planned. Blowdown was with bottom tapping, in the course of which we tapped all the hot metal from the hearth.

Here again, reinforcement of the skip bridge was as important as the reconstruction of the blast furnace. Shortening of the reconstruction time was enhanced considerably by scraping out quickly the material remaining in the hearth, by the good work of KGYV [expansion unknown], and by efficient preparations and work organization.

Parallel with the reconstruction of the blast furnaces we have rebuilt so far three of the heating stoves. In view of this it is feasible to plan to maintain continuously a blast temperature of 950°C, and parallel with this we can increase to some extent also the injection of natural gas.

The No III blast furnace, which offers the most possibilities, is the centerpiece of our plans. Even at present this blast furnace accounts for about 55 percent of our total output, and after its expansion this proportion will increase to between 70 and 75 percent. In other words, the converter plant will be supplied predominantly by the No III blast furnace.

Until the commencement of the blast furnace's reconstruction (in July 1980), however, maintaining reliable operation of the furnace built in 1975 will require considerable effort, because in 1977 and 1978 significant deformation and cracks appeared in the jacket, due to the worn-out bosh brickwork and shaft lining.

Having repeatedly reinforced the jacket, in March of 1979 we installed a new top and simultaneously undertook extensive reinforcement of the jacket, in the case of the bosh jacket by so-called pocket patching, where pockets joined to the existing jacket are filled with refractory cement.

To form a more centered blast for the purpose of protecting the jacket, we replaced the earlier 150-mm diameter tuyeres in the blast furnace with 130-millimeter ones, but this necessarily resulted in a reduction of the output and of the production rate, and a worsening of the coke-burning rate.

Work has already begun on the foundation of the fourth heating stove, and its construction will be completed foreseeably by mid-October 1979.

The heating surface of the checkers installed in the new stove will be 27,100 square meters, as compared with 12,800 m^2 in the present stoves. The checkers will be built of honeycomb checker bricks of the F_2 type, and the specific heating surface will be nearly double the heating surface of our present stoves.

After the construction of the new heating stove and the reconstruction of the three present stoves according to the same modernized design, the specific heating surface per cubic meter of working volume will increase from 50 m^2 at present, to about 100 m^2. With four-stove operation we must increase the blast temperature from 950-1000°C at present, to 1110-1150°C, and parallel with this the injection of natural gas also must be increased at the technologically feasible rate, to between 90 and 100 m^3/t at NTP.

The capacity of the purchased Japanese-Lang axial blowing machine that will be installed in the new blast furnace will permit also a certain increase of the production rate.

The converter plant by its very nature demands uniformity of the hot metal's composition, and the present variation in the composition of the blast-furnace product cannot be tolerated in this steelmaking installation. To ensure the required quality, therefore, at the No III blast furnace we will improve the accuracy of weighing the charge and the coke:

By equipping the ore-weighing cars with electronic scales;

By weighing also the coke electronically and using supplementary automatic control equipment to continuously correct variations in the coke's moisture content.

We are assigning an important role also to evaporative cooling. Parallel with the evaporative cooling system we are planning to install a closed cooling system for the tuyeres, and in 1981 we will introduce a new tuyere design built on the basis of a Soviet license. This will reduce the burnout of the tuyeres and will thus increase the reliability of operation.

Startup of the new steel plant and parallel operation of the open-hearth steel plant will create a peculiar situation in handling the hot metal. Seventy-ton ladles can be hoisted only in the Integrated Steel Plant. Because of the differences in the provisions for receiving, temporarily it will be necessary to use both 50- and 70-ton ladles.

With the realization of the measures and investments briefly outlined above, we will be able to supply hot metal for the converter plant at a technologically suitable level. Simultaneously, of course, also the technical level of our pig iron production will improve, optimally under our conditions. This can best be characterized by the specific coke consumption that basically reflects the technology of ironmaking. In comparison with the present level, at the same charge and coke ratios we are planning a reduction of between 40 and 50 kg/t in our specific coke consumption by 1981-1982.

The production of gray pig iron is a serious problem. After startup of the converter plant, the Lenin Metallurgical Works will not have any surplus hot metal, because the entire quantity will be necessary for the converter that will gradually be increasing its output, and for the open-hearth furnaces.

Because the other two metallurgical enterprises also will have shortages of hot metal, in my opinion it is necessary to investigate whether the foundries' entire demand for gray pig iron could be supplied from import.

In addition to the plans for technological development, mention should be made also of the question of replacing skilled manpower. In comparison with the manpower shortages in other areas, this is a more serious problem in the ironmaking trades. As a stop-gap solution we will request the workers of our factory unit to complete training courses for skilled workers in iron-making, offering them time off and leaves of absence for study, so that they may master their trades as thoroughly as possible.

Our enterprise recently commemorated the centennial of the commencement of open-hearth steelmaking. During this period the plant underwent considerable development, and its development has been rapid particularly since 1945 (Fig. 1).

Figure 1. Development of the plant's steel output: a - output of open-hearth steel; b - output of electric steel.

Key:

1. Output, 1000 tons 2. Year

Postwar reconstruction and economic growth required ever more steel. The high quantitative demand necessarily led to the modernization and development of the steelmaking installations. As a result of the necessary measures and of the metallurgical experts' modernizing efforts, we were able to achieve already in 1947 the open-hearth steel output of 1938, the last prewar year. From then on the quantitative increase of our output may be regarded as continuous, except in one or two years.

In the open-hearth steel plant the No 9 furnace, with a rated capacity of 80 tons, has been placed in operation. The Nos 1, 2 and 3 furnaces have been in operation since 1951. The No 4 furnace, a 180-ton tipping unit and Hungary's largest furnace at that time, was commissioned in 1952. In 1954 we switched from generator-gas firing to firing with fuel oil residue,

and we installed dampers that ensure rapid changing of the cycle. In 1959 we developed the conditions for combined firing with natural gas and fuel oil residue, and we modernized the supply of furnace air. We installed modern, dual atomizing burners for the new mode of firing. A significant technical measure in 1960 was that we increased the weight of the charge in a few furnaces, and simultaneously three-ladle tapping became feasible with the help of a tilting runner. The latest development in the open-hearth steel plant was in 1977-1978 when, in addition to investments for conservation of the equipment, we modernized the furnaces' measuring instruments and we also installed new safety equipment.

Development of electric steelmaking was similar to that of open-hearth steelmaking, as the production curve of electric steel unambiguously shows.

To develop our output of high-grade steel we commissioned two 10-ton Tagliaferri electric furnaces in 1951, and one DSZP 50 arc furnace in 1969. This 50-ton furnaces is our most modern steelmaking installation at present.

To satisfy the ever-higher quality requirements parallel with the quantity of production, in 1967 we decided to install vacuum-degassing equipment in the technological process of steelmaking at our electric steel plant.

In addition to increasing the quantity of production, we considered it our task to supply also the ever-higher qualitative demand. This was not an easy task, because our product structure is very diverse (see Fig. 2).

Approximately 1100 grades of steel are produced, including nearly 600 alloy steels.

To improve the quality we introduced modern steelmaking technologies suitable for our conditions. For example:

Special methods of deoxidation,
Treatment with synthetic slag,
Microalloying, and
Vacuum degassing.

Figure 2. Product structure of the steel plants.

Key:

1. Open-hearth plant
2. Rimmed steel
3. High-grade carbon steel
4. Plain carbon steel
5. Electric steel plant
6. Medium-alloy steel
7. High-alloy steel
8. Castings
9. Low-alloy steel

In the present situation, however, we are unable to fully supply every demand.

Development objectives (investments, licensing agreements, etc.) in manufacturing, and here I have in mind primarily engineering and the automotive industry, do not always take into consideration the possibilities of domestic

ferrous metallurgy. In many instances the steelmaking experts are faced with accomplished facts. Such development projects that are not adequately substantiated from the viewpoint of basic materials place a heavy cost burden on the steelmaking plants, because we are able to supply some orders only by repeated reworking.

The strict quality specifications and the new testing regulations can be met economically only with special processes, for example, with electroslag remelting, and their investment costs are substantial. This circle of problems includes, for example, turbine axles, special chemical-industry and reactor-technology installations, high-speed and tool steels, etc.

Despite our existing problems and relatively obsolete production installations, the quality of our products has nevertheless improved, or we have started the production of new, modern products. One such product is ZF steel that we use to make modern synchronized transmissions. By alloying with boron we improve the core strength and toughness, respectively the dynamic breaking force that characterizes toughness.

For chemical-industry investments, in accordance with the users' needs, we developed experimentally the basic material for forged rings of high yield strength and good weldability.

In our experiments we employed microalloying with niobium and vanadium. Under the influence of microalloying the size of the ferrite grains increased from the customary Nos 5-7, to 10, and the breaking force at 80°C was 2.8 m.kgf.

We conducted experiments with rare-earth metal alloy (mischmetall). The results of these experiments were utilized in making cranckshafts. The impact strength improved considerably, and its anisotropy declined significantly.

To improve the quality and economic effectiveness of our steelmaking we are undertaking our largest investment so far: the construction of an integrated steel plant, in two phases.

An L-D converter and a ladle-finishing facility are being built in the first phase.

The L-D converter operates in a spare-converter system, i.e., one converter is always in operation while the other converter is undergoing repair or serves as standby capacity. The converter's heat size is 80 tons, and its working volume is 68 m^3. The oxygen is blown in at a maximum rate of 300 m^3/min at NTP. The oxygen consumption per ton of steel is 52 m^3 at NTP.

For teeming there are eight transverse teeming stations, each accommodating two ingot cars on which the 6.5-ton ingots are teemed into molds, seven molds per stool. The ingot cars are moved in pairs by a haulage system from one hall to the next, in accordance with the technological sequence.

The molds are stripped with the help of two types of stripper cranes. VALMET [expansion unknown] straddle trucks transport the ingots to the roughing mill.

The requirements with respect to steel quality necessitate that we reduce the steel's sulfur content to a minimum. The effectiveness of desulfurization in the L-D converter is rather limited, about 40 to 60 percent. This is related to the following factors:

Basicity of the slag,
CaO/FeO ratio, and
Initial sulfur content of the hot metal.

We will install a stirring-blade desulfurizer to reduce the sulfur content of the hot metal. We plan to use powdered lime as the desulfurizing agent, and nitrogen as the carrier gas. Approximately 50-percent desulfurization can be achieved in the hot metal. With preliminary desulfurization, then, we expect to reduce the sulfur content of the hot metal to 0.025 percent. If we take into account that 40 percent further desulfurization can be achieved in the converter, the sulfur content of the finished steel will be approximately 0.015 to 0.018 percent. Further desulfurization can be achieved only with ladle finishing.

The main items of equipment for ladle finishing, and the operations that can be performed with them are as follows:

The ladle-finishing vessel has a capacity of 80 tons of steel.

A built-in induction stirrer stirs the steel. The effectiveness of stirring is enhanced by argon injection through the porous brick installed in the bottom.

The heating section has a transformer rated at 8 MVA, and a heating rate of 3 to 5°C/min can be attained with it. Preliminary heating occurs at atmospheric pressure.

The vacuum chamber is equipped with mercury-vapor pumps, charging lock, vacuum lines, and an oxygen lance that is necessary for refining. The lowest attainable vacuum is 0.5 mm Hg.

The ladles are of the gate-valve type, and their approximately 1 m^2 surface is made of austenitic steel.

The ladles are moved in tipping ladle-cars. The tipping angle is 50°, the speed is 12 m/min.

The following operations can be performed in the ASEA-SKF ladle-finishing facility:

Temperature equalization,
Vacuum degassing,
Desulfurization,
Deoxidation,
Alloying,
Slag treatment,
Vacuum refining, and
Casting.

The facility offers great flexibility from the viewpoint of both technology and programming, because it can be combined with any one of the primary smelting installations.

In sum we may say that the feasibility of combining ladle finishing with any of the smelting installations is unambiguously economic, particularly if we take into consideration the quality-improving effect.

In July 1979 we concluded a contract for the construction of the second phase. An arc furnace with a high production rate, and a continuous casting machine will be installed in this phase. The equipment is being supplied by two Japanese companies: Kobe Steel, and Nippon-Kokan. The arc furnace is of the Toschin type, its rated output is 220,000 TPY, the heat size is 80 tons, the transformer is rated at 36 MVA, and the heat time is at most one hour.

The production rate is enhanced by the three gas-oxygen burners installed in the sidewall of the furnace.

The furnace has a jacketed shell and is designed with a special wall-cooling system to reduce wear of the refractory lining to a minimum.

Figure 3 shows the development of a Toschin furnace's annual output and production rate; Fig. 4 shows its power and oxygen consumption, and Fig. 5 shows its refractory and electrode consumption.

The diagrams contain the specific production data of a 70-ton furnace built in Japan.

An important unit of the second phase will be a continuous casting machine.

The continuous casting machine will be a five-strand unit on which we will cast billets 120, 150 and 180 mm in diameter.

The capacity of the continuous casting machine is 350,000 TPY. It is designed with a curved crystallizer of the radial type. The nominal radius is 10 m, and the machine's metallurgical length is 16 m. To avoid oxidation of the casting radius, a protective atmoshphere of argon gas is planned between the pouring ladle and the tundish, and the tundish and the crystallizer. Each strand is equipped with an electromagnetic stirrer in the

secondary cooling zone under the first row of rolls. The casting rate may vary from 1.0 to 2.4 m/min, depending on the quality and the billet size.

The flow of materials between the integrated steel plant's producer and teeming/casting units requires well-coordinated and organized work (Fig. 6). The many variations possible unquestionably necessitate a computerized process control system, which we have already ordered from the mentioned Japanese companies.

Figure 3. Development of the heat time (tap-to-tap time), production rate and annual output of a 70-ton electric arc furnace in steelmaking: a - annual output per furnace; b - production rate, t/hr; c - tap-to-tap time, minutes.

Key: 1. Tons/year
2. Tons/hour
3. Time, minutes
4. Year

Our experts are preparing systematically for the operation of the integrated steel plant. The most important task at present is to elaborate the technology for the first phase, which will be the basis for further organizational, technical and labor measures.

To this end we are researching, with the participation of outside institutes, the technological processes of converter steelmaking, the solubility of the scrap and lime, and the feasibility of using domestic refractory materials. We regard as a task of outstanding importance the elaboration of teeming technology and the supply of suitable teeming fixtures for the teeming bay. We are conducting extensive studies and experiments to prepare the production of teeming fixtures, stools, molds, refractory materials and hot tops.

DEVELOPMENT PLANS AT CSEPEL DISCUSSED

Budapest KOHASZAT in Hungarian Nos 3-4, Mar-Apr 80 pp 124-126

[Report by Ervin Proszt, technical director of the Csepel Steel Mill: "Problems of Developing Steel Production at the Csepel Steel Mill"]

> [Text] The report strongly emphasizes that the entire demand for starting materials to make seamless tubing must be supplied from steel produced in Csepel. A new electric steel plant, equipped with ladle finishing and continuous casting, must be built to produce 300,000 tons of molten steel a year.

Steelmaking in Csepel has traditions of long standing, and steel is being made here since World War I. In the meantime--similarly as at Hungary's other steel plants--the output of open-hearth steel and electric steel was increased on several occasions. This was achieved by increasing the heat size of the furnaces, expanding the furnace plant, building new steelmaking furnaces, and introducing other measures.

During the past decades our steel mill introduced numerous technological changes. Noteworthy among these was the fact that in 1935-37 we were the first in Central Europe tc introduce oil firing and the basic-brick roof.

We were the first in Hungary to introduce mechanical chilling of rimmed steel with bottom teeming into big-end-down molds.

From the very beginning a principal task of our steelmaking was to supply suitable starting material for the country's only seamless tubing mill. Over the years we were able to easily meet the strict quality specifications for the cast round billets for tubes, and in more than 90 percent of the cases the tube mill was able to use the billets with their surface as cast. Over the years we developed the technology to produce the starting material for boiler tubes of suitable quality.

In addition to supplying billets for the tube mill, our steel mill supplied with starting material also the other ferrous metallurgical plants in

Csepel, including the steel foundry, the roughing mill, small-section mill, sheet mill, the forging plant, the production of high-pressure steel bottles, and welding electrode factory.

Over the years we closed down three rolling mills, but in spite of this the demand for steel starting material increased and the CSM [Csepel Works] Steel Mill, in the absence of suitable expansion, was unable to satisfy the demand. For this reason we procured ever more steel from outside sources. At present we are producing 190,000 TPY in our four 50-ton open-hearth furnaces, and 40,000 TPY in our three electric arc furnaces.

We are using starting material supplied by LKM [Lenin Metallurgical Works], OKU [Ozd Metallurgical Works] and DV [Danube Iron Works] among the Hungarian metallurgical enterprises, and by the Soviet Union, East Germany, Poland, Czechoslovakia, Bulgaria and Yugoslavia among the socialist countries. In terms of steel, the Csepel Works' total demand for starting material is about 530,000 to 540,000 TPY.

Within the total steel consumption of the Csepel Works, the production of seamless tubing requires 260,000 to 270,000 tons of starting material a year, and thus its share of the total demand amounts to 50 percent. Also for this reason the tube mill's demand for starting materials is decisive from the viewpoint of steelmaking technology, the size of the installations, the quality specifications and, last but not least, also from the viewpoint of managing production.

To substantiate the above statement regarding the management of production we wish to note the following:

The tube mill's four pilger mills require 13 grades of rounds in seven sizes ranging from 105 to 160 mm in diameter, an assortment of 55 different products.

The requirement for round ingots must be supplied in ten different grades and eight sizes ranging from 220 to 430 mm in diameter, an assortment of 49 different products.

The two push benches requires 79,000 tons of A 35 grade steel, in four sizes of billets ranging from 90 to 145 mm in diameter.

From these figures it is evident that the supply of the tube mill with starting material is no small task also from the viewpoint of managing and scheduling production, which can be ensured only through close cooperation between the two mills.

In conjunction with supplying the steel requirement of the Csepel Works, the problems of maintaining our open-hearth steelmaking arose already under the Fourth Five-Year Plan.

When KGM [Ministry of Metallurgy and Engineering] set the investment objectives for Hungary's iron and steel industry, it targeted the continuation of open-hearth steelmaking in Csepel until 1983 and agreed that until then production had to be ensured with upgrading investments that did not call for any expansion of production capacity. By its resolution adopted in 1974, the Council of Ministers allotted 311 million forints from the state budget for upgrading investments. The purpose of these investments was to reduce the amount of heavy physical labor, to improve working conditions and to resolve the manpower shortage.

Through the realization of the investments we reduced our manpower demand by 118 workers or 15 percent. With a new scrap-shearing machine we improved scrap preparation, and we mechanized the handling of the auxiliary and added materials. We replaced the two manually charged 5-ton arc furnaces with a modern 10-ton furnace equipped with a dust catcher. In addition, eight charging and travelling cranes were placed in operation, and the worn-out trackways of four cranes were reinforced. To improve the conveniences for the workers, we built a new lounge and cafeteria.

Without these upgrading investments it would not have been possible to maintain the four furnaces in operation to this day, and to avoid a drop in production of about 50,000 to 60,000 tons of steel a year.

However, the investments were unable to remedy the basic drawbacks stemming from the obsolete location and obsolete technological installations of the open-hearth plant that was developed during World War I and gradually expanded.

Overcrowding, heavy physical labor, the danger of accidents, and manpower shortage characterize our open-hearth steelmaking also at present. As an example of overcrowding I wish to note that significantly more ingots are teemed each year in Csepel than at other domestic steel plants with much higher output.

About 245,000 ingots are teemed each year at the Csepel Works, as compared with 200,000 at the Ozd Matallurgical Works, 42,000 at the Danube Iron Works, and 140,000 at the Lenin Metallurgical Works, in teeming bays substantially larger than the one in Csepel.

Despite the upgrading investments and other adopted measures (regrouping of manpower and wage measures), we have not been able to arrest the decline of the labor force. Because the new workers are inexperienced, the danger of accidents has also increased.

Upgrading investments are in progress to ensure also the further operation of our tube mill that has been producing for more than 50 years. At a cost of about 1.5 billion forints, these investments will be realized by 1981. Tied in with these investments is also the modernization of tube production, by building a new tube mill, the development objective for which has been

approved by ATB [State Planning Commission], but with the stipulation that the question of supplying the starting material must be resolved in the course of elaborating the investment proposal.

Our domestic metallurgical plants are unable to supply the starting materials needed for tube production. Therefore the Ministry of Metallurgy and Engineering, in agreement with the decision of the State Planning Commission, entrusted the mangement of the Csepel Works to prepare a target study on the development of steelmaking. The ministry prescribed two alternative sites: one the existing open-hearth steel plant and its vicinity, the other land available in the southern section of the Csepel Works.

The first site variant was not elaborated, because expert opinion held that the buildings of our open-hearth steel plant were unsuitable for 25 to 30 more years of operation, and because the site's small area and layout would have been unsuitable anyhow for the proposed technology.

For these reasons the target study on the development of steel production was elaborated on the basis of the second site variant, and in this study the target was to supply the entire demand of starting materials for the production of seamless tubing.

The target study on developing a new electric steel plant was ready by the end of September 1978. As the site of the 350,000 TPY electric steel plant it considers the land available in the southern portion of the Csepel Works.

The task of the new steel plant will be to supply the entire starting material required for about 250,000 TPY of seamless tubing produced in a new tube mill to be built in the area of the old tube mill. The 6-inch push bench will require 240,000 TPY of continuously cast billets 180, 200 and 240 mm in diameter, and 85,000 TPY round ingots from 200 to 450 mm in diameter. The continuously cast billets must be supplied in the aforementioned three sizes and in 16 grades, an assortment of 40 different products. The round ingots must be produced in five sizes and 13 grades, an assortment of 52 different products.

For steelmaking the study considers two UHP arc furnaces and the oxygen-oil-gas auxiliary burner variant. To the steelmaking technology we will be able to add also ladle-finishing equipment. Today ladle finishing is a practically indispensable phase in the technology of making modern high-quality steels. After development, approximately 40 percent of the tubing produced in the tube mill will have to meet high quality specifications.

The application of ladle finishing is unquestionably warranted to improve, and to narrow the variations of, the longitudinal and transverse mechanical properties of high-strength oil-industry pipes, boiler tubes, and cold-drawn special tubing.

The steel will be cast in a three-strand continuous casting machine, respectively it will be teemed into ingot molds by mechanized teeming. We took into consideration also the casting of three successive heats in the casting machine, so that every fourth heat will be teemed into molds. We plan to computerize process control and the scheduling of melting, ladle finishing and casting. In addition to the principal production installations and auxiliaries of the steel mill, other supplementary investments also will be necessary. These include storage bins for the added materials, terminals for the power supply and natural gas, dust-control equipment, waterworks, sewage plant, conveniences for the workers, etc.

The manpower requirements for the new steel mill will be 480 workers. At current prices, the cost of the investment will be 5.4 billion forints. We hope to realize this investment within 2.5 to 3 years from the commencement of site clearing. Scheduling of the investment in the new steel plant must be coordinated with progress on the construction of the new pipe mill, and the investment will have to be subdivided into phases.

The limiting conditions of subdivision into phases are as follows:

Availability of financial resources,
Uninterrupted vertical production relations,
Economic product structure even if the vertical production relations are expanded in stages,
Even production rates, without production dropouts.

At the end of 1978 the management of the Csepel Works reviewed the complex plan for the development of steel production and tube production, because of changes that occurred in the conditions of development and in order to further reduce the investment costs.

Among the changes that occurred in the conditions of development, the priority of developing the production of cold-drawn tubin, the possible site of the tube mill's captive steel production, and the need of ensuring the economic effectiveness of the vertical production relations raised the question of developing a new site. A new proposal was elaborated that called for locating the 6-inch push bench at a new site, in the immediate vicinity of the steelmaking base. The great advantage of this new site manifests itself in that the hauling of the 240,000 TPY of starting material for the push bench would be eliminated, and production cooperation between steelmaking and the output of tubing could be ensured. The supplementary investments associated with steelmaking (sewers, water supply, installation of electricity and natural gas, etc.) could be shared by the new integrated steel plant and tube mill, resulting in lower investment and operating costs and in a reduction of the manpower requirement.

As a further advantage for the tube mill, the investment would disrupt production of the mill's existing facilities not at all or only to an exceptionally small extent, and in this way the very costly and unforeseeable temporary solutions and shutdowns could be avoided. Another advantage of a

common site is that the conveniences for the workers could be shared, permitting a reduction of the construction costs. Furthermore, control of the entire integrated operation could be computerized, enhancing maximum utilization of capacity and optimal costs.

(The concept outlined above has not yet been approved by the management of the Csepel Works.)

In conjunction with the 311-million-forint upgrading investments in our steel mill, I mentioned that the investments only served to alleviate the manpower shortage but were unable to arrest the decline of the labor force. Our present 18 percent vacancy rate is already jeopardizing the further operation of our open-hearth furnaces. Our steel output will decline considerably in 1980, which will cause a serious problem in supplying starting materials for the tube mill. Maintenance of production will depend on the further development of the work force. Reduction of the steel output in Csepel would further intensify Hungary's steel supply problems.

Seeing the present serious situation of our steelmaking, the management of the open-hearth plant ordered the elaboration of a two-phase variant for developing the production of electric steel.

In the first phase our present output of open-hearth steel would be discontinued, and the new steel plant's output would be 200,000 TPY, which would ensure starting materials for the tube mill at the present level of in-house supply.

The steel plant would include an electric arc furnace, a ladle-finishing facility, and continuous casting.

The first phase would be realized on the site proposed for developing the 350,000 TPY output of electric steel, in such a way that the realization of the second phase would permit operation at full capacity. In this case the second phase of steelmaking would adapt to the realization of the development of tube production, ensuring the technological integration of the two plants.

With the realization of the first phase, then, our open-hearth plant would be shut down in such a way that the Hungarian iron and steel industry would be relieved of supplementary tasks that do not belong in its product mix. In August of this year the Metallurgical Committee of the Iron Workers Trade Union debated the problems of steel supply in Csepel.

Representatives of MVAE [Hungarian Iron and Steel Association], Danube Iron Works, Ozd Metallurgical Works, Lenin Metallurgical Works, and Csepel Works also were present at this session. A consensus developed that Csepel's steel supply could be solved only through investments. The conditions of Hungarian steelmaking do not permit the supply of small round ingots for the production of tubing in Csepel, and if steelmaking in Csepel is discontinued, the supply of the tube mill with starting materials cannot

be ensured. There was also agreement that open-hearth steelmaking in Csepel can be phased out the most expediently and at most favorable outlays--taking also the transportation costs into account--by realizing the first phase of the development of electric steel production in Csepel.

The investment cost of discontinuing open-hearth steelmaking in Csepel--i.e., of realizing the first phase--is 2.992 billion forints at 1978 prices. The manpower requirement is 350 workers, while the manpower requirement of the remaining electric furnaces is 130.

The plan outlined above dovetails with the concepts for developing ferrous metallurgy in Hungary. It economically ensures the Csepel tube mill's supply with starting materials. And last but not least, it realizes also in our steel plant the "technological change" that unquestionably will be necessary in the near future, for reasons of economy and of supplying high-quality materials.

ENTERPRISES TO COLLABORATE IN PRODUCTION OF COSTLY CHEMICAL INTERMEDIARIES

Budapest NEPSZAVA in Hungarian 16 Aug 80 p 3

[Article by Tibor Flanek: "Integration in the Large and the Small"]

[Text] One of the critical problems in the development of the Hungarian pharmaceutical industry and the related manufacture of herbicides is undoubtedly where, how, and mainly for how much it will be able to obtain those chemical intermediaries of complex composition and almost unpronounceable names for which individually there is no great need, but which, in their totality, represent one of the most important expenditure entries in the export-import balance of that industrial branch. We spend annually several tens of millions of dollars to acquire these products. Thus the improvement in the economy of our pharmaceutical industry is made difficult not only by a range of products which is wider than that of the international monopolies themselves, but also by the relatively high proportion of preparations manufactured in small numbers and at low profitability, if not loss. The different kinds of starting materials also cause great problems.

In theory, one could do something about this. Modernization of the product structure, termination of production at a loss is nowadays as much a task of the pharmaceutical industry as of any other branch. And we cannot say that we have not seen such efforts. But in addition to the economy requirements, the pharmaceutical industry must take another factor into account. Namely, that besides its obligations to the national economy, it also bears responsibility for the domestic pharmaceutical supply.

The Supply Responsibility

The pharmaceutical industry cannot withdraw this or that product from the market because it is selling at a loss. We are aware that such a step can cause problems even in the case of less vital items—for example, a shaving soap one has become accustomed to, or a shoe polish—but in the case of medicines this is simply not permissible.

Of course, socialist integration and international cooperation are available. In fact, we have already signed specialization agreements with the

Soviet Union and other socialist countries. These are working well, but there is little possibility that they can be expanded at a rapid rate for the time being. And there are capitalist imports, but we must take into account the fact that from the developed capitalist countries we buy pharmaceuticals at a cost two to three times higher than our own.

The Hungarian pharmaceutical industry resigns itself to this situation when, to protect the price level and moderate the country's import expenditures, it continues to manufacture products at the lower level of rentability, or even below it. Besides further investigating the possibilities of integration, they are seeking to improve profitability primarily by reducing costs as well as by introducing new, original Hungarian preparations on the world market.

One path of development, therefore, is more intensive research and an active market policy; and in production, the improvement of technologies and a more modern organization. The other course--where the reserves are greater--is for us to obtain, or manufacture domestically the in-between products, the so-called intermediaries, which serve as the starting materials for pharmaceutical and herbicide production.

It is not without reason that recently the organization of the domestic manufacture of intermediaries has come to the center of attention. Some of them are already made here at home, and thus there is a realistic basis for the development. But the Hungarian chemical industry will never be able to manufacture all of them because it is necessary for the pharmaceutical and herbicide industry, and the paint and plastics industries to have several hundred different kinds of compounds. On this long list there are some for which a whole year's requirement is measured not in tons but in kilos.

But all in all, these kilos also represent a very heavy import burden for the economy. Moreover, the foreign firms do not sell such materials willingly, because when they process them further they can make a much greater profit on the finished product. The security of pharmaceutical manufacture as well requires that--if at all possible--we solve the problem of domestic manufacture.

Successful Export--With Question Marks

The fact that the basic materials are also available to us suggests that we organize the manufacture of the most important intermediary products. These are petrochemical products and it would have been possible to conceive that the also otherwise successful petrochemical central development program would have extended in this direction. But there was not enough for all this, and the domestic plastic manufacture development was at least as important. Today the results that the manufacture and export of ethylene, PVC, and polypropylene have developed on a petrochemical basis should clearly improve the payments balance of the economy.

So-called aromatic products obtained in the process of petroleum refining also are successful export items and marketable at good price. There is, for example, benzol and toluol. But it quickly becomes evident that it is not such a great business to sell these products if we consider that the Hungarian chemical industry buys abroad at terribly high prices the intermediary products that are made from them. As a matter of fact, it is with the use of benzol derivatives that the Hungarians make such medicines as Papaverin, No-Spa, and Dopegyt, and herbicides like Fundazol and Propaklor. Sevenal, Noxiron, Fenilglicin, Halidor and Chlorocid are made from intermediaries with a Toluol base, as well as a series of paint colors and the PVC emollient.

These are only several examples out of many. All of them show that in the final analysis even exports that appear to be good for the economy are not always market bombshells.

Of course, the dimensions of our chemical industry and our pharmaceutical and herbicide industry are dwarfed alongside those of the large international monopolies. What they can do--control the entire production chain from the basic material to the final product--is not possible for Hungary. Or at least not in every area. If we want to narrow the production scale of the pharmaceutical industry, we cannot fall into the opposite extreme in case of the chemical intermediary products.

Without Being Exploited

But there is a rational middle course. The manufacture of the most important intermediaries necessary in the largest volume can be solved. Under the guidance of the Ministry of Heavy Industry we are realizing one-half billion forint investments each at the Borsod Chemical Combine, at the Fuzfo Nitrochemical and the Pet Nitrogen Works, and thus with the beginning of the next plan period more than $10 million in imports will become necessary.

We have not given up on the production of the intermediaries used in lesser volume, since these also represent a burden of many billions of dollars. But this cannot be centrally guided, and there is no material cover for additional and significant investments. But the ideas of various sized collectives, of specialists working in research institutes or cooperatives, or of private persons can make possible the savings of additional millions of dollars. The ministry is giving incentive with competitions to the realization of such ideas as do not require investments.

The essence of the matter is that in the narrow sense of the word it should be possible to moderate the burdens of the economy with social forces as well. It is worthwhile to manufacture certain intermediaries even in laboratories. It is not the volume, but the value that is important.

Of course, economy is the basic requirement. Therefore we cannot strive for complete self-sufficiency. We must exploit our own possibilities better, as well as the advantages in international cooperation. A good example is the cooperation between the Budapest Chemical Works and an Austrian firm: in return for the intermediaries manufactured in Hungary, the Hungarian party receives end-product herbicides.

Similarly, the true, long-term solution must be based on mutual advantages and interdependence. This is the one way in which we can put an end to frequent vulnerability to exploitation and obtain at realistic price, and with certainty of supply, everything which Hungarian industry, agriculture and consumers need.

BROADER, STRICTER GRADING OF WHEAT ADOPTED

Budapest FIGYELO in Hungarian 30 Jul 80 p 11

[Article by Dr Jozsef Bagi: "The Quality of Wheat"]

[Text] In the course of the past decade, our grain production has increased significantly, and did so primarily because of an increase in yield, and not because of the extension of the land under cultivation.

During the period of the Fourth Five-Year Plan, the yield of wheat increased at an average annual rate of 4 percent. During the Fifth Five-Year Plan—discounting the past year with its unfavorable yield—this increase in production continued.

In 1979, after several years of preparation, the Council of Ministers passed a resolution ordering the purchase of agricultural products to be done in accordance with their quality. In line with this resolution by the Council of Ministers, this system of purchase based on the product's qualities must be further improved. A resolution by the Ministry of Agriculture and Food Industry for the year 1980 makes it obligatory for all wheat to be purchased purely on the basis of qualitative considerations. These resolutions by the Council of Ministers and by the Ministry of Agriculture and Food Industry place significant goals before all agricultural establishments, as well as before the county purchasing branches of the Grain Trust. The species composition of the winter wheat sowings for 1979 indicates that the area devoted to the growing of better quality improved-wheat has increased considerably.

The system that has been used up to now to classify wheat evolved during the 1950's. Ever since that time the emphasis has been on producing better quality wheat even though this meant a relatively low yield. Moreover, the country's wheat production was dominated only by one or two species. The inner qualities of these species were more stable, and they satisfied all of the qualitative requirements. Thus, at the time of their classification, emphasis was placed only on the examination of their storing and their milling capacities. Their inner quality was examined only through random samplings.

The quantity of current production exceeds the domestic demands, but this quantity is achieved only through advanced agricultural methods, and through the production of about 20 different species of wheat. As such, the quality of wheat production varies from species to species, from region to region, and in many instances also with the agrotechnical methods used.

Consumers' needs have also changed. The rise in the quality of life produced higher qualitative expectations, and the earlier quantitative problems were replaced by qualitative expectations.

The New Classification System

According to the new classification system, the pruchase of the wheat is accompanied by a laboratory examination of the species, its water content, its mixability, its weight per hektoliter, its ability to withstand insects, its wet gluten content, its backing quality, and its enzyme status.

Many years of experimentation have proved conclusively that quality depends basically on the species. Low yield of good quality wheat is usually the result of agrotechnical and harvesting errors. At the same time, low quality wheat will never yield high quality products. The new regulations concerning wheat quality and wheat pricing distinguishes between three types of wheat: Improved food wheat, customary flour wheat, and fodder wheat.

The system of purchase based on the examination of the species and of the wheat's makeup was preceded by 2 years of experimentations. In 1978, this systematic comparative examination was conducted at the country's 25 large purchase depots, while in 1979 it was already being done at 30 places. On the basis of these examinations we have identified those improved species that yield the highest qualities. The GK-Tiszataj, the Martonvasar, and the Partizanka types proved to be the ones with the highest gluten content and with the best baking quality in every region. In good wheat-growing regions and with acceptable agrotechnical methods, the Yubileynaya type was also able to fulfill the quality requirements. Besides species and agrotechnical methods, quality is most influenced by the agricultural region. The gluten content of the GK-Tisztaj type, was between 21 and 43 percent.

The wheat's baking quality is also influenced by the region's climate, as well as by the harvest time. With untimely harvesting and with badly executed artificial drying, one can destroy even the best quality crop to such a degree that it becomes unfit to be used as a food product.

[Purchase and Prices]

This year the wheat is being classified in 102 laboratories. The method of classification is in accordance with the norms and the price regulations. Within 15 days of having received the samples, the results of the tests are

available to the agricultural enterprises. Disagreements are being judged and decided by the County Institute of Food Inspection and Chemical Analyses. Purchase is being conducted at about 1,000 separate places. The purchase capacity is indicated by the fact that, on the basis of 12-hour work day, the Grain Trade and Mill Industry Companies of the individual counties are able to handle 300,000 tons of wheat per day.

The stabilization of the production is underscored by the fact that, in the course of the past 10 years, the size of the wheat-growing area remained basically constant at about 1.3 million hektares. In 1980, the effective purchase price of fodder wheat 15 280 forints per quintal, flour wheat costs 310 forints per quintal, and of improved food wheat costs 325 forints per quintal.

Higher purchase prices are in the interest of all agricultural producers. But they receive this higher price only for the production of high quality wheat. In the course of the past few years, the size of the yields in large-scale production has developed approximately the same for all three of these wheat types. This all seems to prove that our current and long-range "species policy," i.e. the availability of better-quality species of wheat, will continue to ensure higher quality and larger yields in the future.

GIEREK-BREZHNEV MEETING VIS-A-VIS POLISH MALAISE VIEWED

Paris LE FIGARO in French 31 Jul 80 p 3

[Article by Denis Legras--passages between slantlines originally published in italics]

[Text] Of all the Eastern Europe party chiefs who, following tradition, have come or will be coming to meet Leonid Brezhnev on the banks of the Black Sea where he is resting, Edward Gierek, who arrived last Sunday, will doubtless get the longest audience.

It may be difficult to discern from the language of a terse communique what is said in secret in the Oreanda villas, but all the same one can speculate that the talks will cover two specific points: the conference on military detente and disarmament in Europe, and the social and economic situation in Poland.

The idea for this forum to bring together the signatories of the Final Act of Helsinki was launched last year in the spring in Budapest, and was taken up by Poland, which volunteered to organize it. Step by step the socialist countries, and above all Poland, are trying to tighten the focus on the main themes, and the means for achieving real military detente in Europe.

The Kremlin gives the impression of leaving all the initiative on this to Warsaw, but from all the evidence it is calling the shots. Leonid Brezhnev, moreover, does not hide this in his "answers to PRAVDA's questions," on the occasion of the 5th anniversary of the Helsinki Accords: /"The immediate objective now,"/ he says, /"is to assure the holding of a European conference on military detente and disarmament .... The important thing is to find the way toward an attenuation of the military threat, now and in the future, to Europe and consequently to the entire world. This goal cannot be achieved if there has not been real progress in the field of limiting the arms race."/

For the Soviets' number one, detente /"can go through ebbs and flows,"/ but the Final Act of Helsinki /"is a good breakwater which resists

anything that undermines the foundations of detente."/ That does not mean, for all that, that the accords signed in the Finnish capital are sufficient by themselves, and therefore we have this proposed conference, which in the Soviet view, while not being a miracle cure, would facilitate limiting the threat of confrontations in Europe. They also thus confirm that in their view detente is divisible.

Ideological Heresy

On the banks of the Black Sea, Leonid Brezhnev and Edward Gierek will try to refine this proposal, which they intend to see presented in Madrid in the fall, and to pin down the areas that could be studied by the experts. Several articles, published by the Polish press have already spelled out the contents: the conference agenda would include, according to the monthly WIDNOKREGI, an extension of the confidence--[building] measures contained in the Helsinki Act, notably with respect to notification and the scale of military maneuvers; but also the elaboration of measures aimed at avoiding [the danger of] surprise attacks, and looking toward a decline in conventional and nuclear armaments.

No doubt when the first secretary gets back to Warsaw, the field of action of this all-European conference will have been sketched out in more detail.

Leonid Brezhnev will change from counselor to inquisitor when the talk turns to purely Polish questions. The Soviet press and the media have maintained a total silence with respect to what is euphemistically called in Warsaw "temporary work stoppages," a silence which in reality is an expression of profound concern. The "Truth in Pricing" program launched by the new Polish prime minister surely met with the approval of his Soviet interlocutors, to the extent that it should permit an economic recovery in Poland. But its social consequences are being watched closely by the Kremlin.

The extremely circumspect way the Polish government is trying to contain the worker protests by "dialog" is certainly appreciated by the Soviet leadership, for it should make it possible to avoid any uprisings like those at Gdansk, Ursus and Radom. But conversely, this form of democracy at the base borders on ideological heresy. In the Soviet scheme of things, the trade union is no more than a relay between government and "the mass of workers;" if it is used in the reverse direction it becomes a disputacious element and loses its role.

Such a situation is unimaginable in the Soviet Union, and is tolerable for Moscow in the countries of Eastern Europe [only] on condition that the movement remains discreet. The example of Hungary should be able to convince Muscovite ideologists that doctrine is basically safe, but will Edward Gierek, who himself must face a demanding Catholic church, be able to walk the same tightrope as Janos Kadar unhindered?

Nothing is less certain. This is what Leonid Brezhnev will doubtless make clear to his guest for a day.

DEMANDS OF STRIKERS NOTED

Paris LE MONDE in French 1 Aug 80 p 4

[Article]

[Text] Warsaw (AFP)--Streetcar workers in the urban complex of Gdansk-Gdynia-Sopot, on the coast of the Baltic Sea, the scene of the events of December 1970, observed a warning strike of half-hour duration on Tuesday, 29 July, it was learned Wednesday, 30 July in Warsaw. The strikers, who are demanding wage increases, declared themselves ready to stop working again if their demands were not satisfied without further delay.

Elsewhere, the 3,000 workers in the DOLMEL factory (electric turbines) in Wroclaw (the capital of Lower Silesia) also walked out Tuesday. They are demanding wage increases, improvement of the [consumer] supplies situation, and alinement of their family allowances with those of the police and the army.

In this latter city, the attempts by the official trade unions aimed at channeling the activist labor movement do not appear to have been crowned with success everywhere. The situation remained confused Wednesday in several enterprises downtown, the workers refusing to let the trade unions defend their demands. Discussions are supposed to be continuing with the leaders concerned, while production continues as before.

GRUMBLING AMONG WRITERS REPORTED

Paris LE FIGARO in French 4 Aug 80 p 4

[Article by Bernard Marguerite--passages between slantlines originally published in italics]

[Text] Warsaw--More and more urgent appeals are making themselves heard in the Polish press for structural reform and a degree of democratization. Following POLITYKA another weekly, KULTURA, has come out clearly in this vein. Pressure for change is also mounting even within the party. One of the best examples of this is the first bulletin published by the party cell of the writers' association.

This bulletin number 1 opens, in fact, with an article signed /"The Executive"/, wherein one reads, among other things: /"We are not satisfied with the conditions of political and material existence of literature in our country. We have said it before, and we will continue to say it."/ The editorial criticizes censorship and proclaims: /"The limits of censorship are debatable, and we will do all we can to put it as far away from us as possible, in accordance with the letter and the spirit of the constitution."/ It is essential, in fact, to /"eliminate the anachronistic and subjective obstacles of censorship."/

The writer Jerzy Jasionowski also addresses this problem:

/"Literary works,"/ he writes, /"are castrated upon the arbitrary judgment of various censors. The same text may be unacceptable in Lodz, but acceptable in Warsaw. As a result, petty officials in the censorship office can decide what of all the literature will be passed on to posterity and what will be eliminated. The more fearful they are, the worse the situation is."/

As for well-known writer and critic Andrzej Mencwel, he raises his voice against the refusal, for years now, [of the authorities] to publish a book by Andrzejewski. He also deplores the prohibition by the censorship office of mentioning the names of certain writers of which the regime takes a dim view, and the prohibition against presenting critical reviews

of works put out by dissidents. These prohibitions, the author says, don't just affect the banned writers. Rather, /"They hit us too, by putting us in an apparently privileged position which, in fact, limits our freedom of action."/

The party bulletin, on the other hand, complains bitterly about the dissidents whom it accuses of /intellectual stalinism in reverse,/ simultaneously showing a certain [attitude of] ostracism towards writers who do not publish in the /underground/ editions, and also producing a literature of strong political coloration which, seen from here, is almost as simplistic as the work published in the Stalin era.

The objective of the writers' association, according to the party cell, is to be a partner in the elaboration of cultural policy: it must continue to act in this direction, even though up to now this goal has not been possible to attain. The writers in the party thus intend, evidently, to make themselves the spokesman for the community of intellectuals vis-a-vis the government, and thereby to succeed in a role which the trade unions, for example, have been incapable of fulfilling with respect to the representation of the workers. One eminent writer, a member of the central committee, summarized in these terms this campaign: /"We have no choice if we want to avoid what happened in Czechoslovakia. If we do not want the writers' association to be taken over by irresponsible revisionists, it is up to us to set the example."/

POLITICIZATION OF STRIKES NOTED

Paris LE FIGARO in French 11 Aug 80 p 2

[Article by Bernard Margueritte]

[Text] Warsaw--Far from fading away, the wave of worker strikes which has shaken Poland for six weeks is only expanding and above all, which is especially disturbing for the government, becoming more and more politicized.

It is estimated, in fact, that about 50 incidents or work stoppages have occurred since the beginning of July. Lastly, it has been the cleaning workers who have gone on strike. Their demands include not only increased wages, better meat supplies and social benefits, but also the demand that there be free elections for union representatives. Very interestingly, these demands have been addressed not only to the government but also to the workers' committee that continues to function in the tractor factories of Ursus, near Warsaw. A second committee of the same kind has held out in Lublin. It too, taking up for example the demands of the 20,000 striking workers for the second time in a month this week at Swidnik, is demanding free elections in the trade unions.

The authorities are more and more powerless, due to their failure to have acted in time to accept trade unions, as in Hungary, that represent the workers' interests while remaining linked to the government. Now they are threatened by the appearance of an authentic movement representing the workers. The ideological and politican danger is indeed great, but the leaders are hardly, in the present state of events, in a position to effectively fight back.

It would, however, be naive to exaggerate the scope of these demonstrations of worker democracy. In 1956 and 1957 very active "workers' councils" were functioning throughout the country. In December 1970 and in early 1971, worker committees were created in the shipyards of Gdansk, Gdynia and Szczecin. In each case, these groups authentically representing the workers were suppressed as soon as the government regained some stability.

However that may be, the strike movements continue, further aggravating an economic situation which is already difficult. According to one well-known Polish personality, the wage increases already granted are going to cost the state budget 20 billion zlotys. Moreover, the bumbling attitudes of the authorities provoke the workers to go on strike. In some cases, in fact, such as in a plastics factory in Silesia, wage increases are being granted only to those workers who have already gone on strike. In other cases, strikers are getting increases greater than those given to non-strikers. Thus in Warsaw's joint transport enterprise, the employees who had struck obtained a wage increase of 1.50 zlotys per hour, while the non-strikers got only an increase of 1.10 zlotys ....

So it is a completely anarchic situation. All this explains why the malaise is becoming more and more perceptible even within the party. The next plenary session of the central committee, which should meet about 5 September, is thus being awaited with growing impatience. The leadership of the party, in effect, will have to resolve to tell the public what it intends to do to get the country out of the grave crisis in which it is becoming more and more deeply enmeshed.

GDANSK REGION STRIKE, PREMIER BABIUCH APPEAL NOTED

Agitation Becomes Political

Paris LE MONDE in French 17-18 Aug 80 pp 1, 2

[Article by Bernard Guetta--passages between slantlines originally published in italics]

[Text] Communications between the city of Gdansk and the outside have been cut since the afternoon of Friday, 15 August. We were able to learn, previously, that the strikers in the Lenin shipyards, whose demands have politicized the present strikes, were followed in a completely peaceful way, by some 30,000 workers from other enterprises on the Baltic port.

The way the prime minister, Mr Babiuch, spoke Friday night on television to the population expressed both the confusion of the authorities and the limits of the possible: without making concessions to the strikers, he only promised to maintain meat prices at their present levels (increased starting 1 July 1980) through 1981. The press and television are stepping up appeals to "self-discipline."

Mr Gierek, the party chief, who had met Mr Brezhnev in the Crimea on 31 July, cut short his vacation in the USSR by 24 hours to return to Warsaw. In Bonn, where developments in Poland are being followed "attentively," it is hoped that there will not be "consequences" for the talks Mr Gierek is supposed to have in Hamburg with Chancellor Schmidt on 19 and 20 August.

Neither in Moscow nor in the other capitals of the socialist community is anyone commenting on the Polish strikes. In Tirana, by contrast, the party organ ZERI I POPULLIT writes that they demonstrate "the hatred and

opposition of the workers to the capitalist, anti-popular, anti-national policy of the Warsaw revisionists."

Warsaw--A month and a half now of repeated and successful strikes. Warsaw without public transport for 4 days this week. And now Gdansk, alarmingly calm, in revolt. All this in a communist country, within the territory of the biggest of the USSR's European allies. Where is Poland headed?

Some shrugging of the shoulders, arms lifted up to the sky, and a poignant murmur /("a catastrophic situation, grave, very grave")/. This is the only response one can pull from official spokesmen. They do not become unstrung; they are not trying in some obscure way to dramatize things. No, they simply do not know; the propaganda department is no longer putting out situation reports on which they can elaborate; and the demoralization of officials is mirrored by the worry of the Poles.

The opposition is no longer garrulous, or sure of itself. It should, however, claim victory. Following the riots of 1976, in efforts to obtain amnesty for the convicted workers, it was down to a handful of intellectuals. It has increased, developed a powerful clandestine press network, and, since 1 July, whenever a new strike has broken out the first action taken by the strikers has been to inform Mr Jacek Kuron, the principal leader of the Committee for Social Self-Defense (KOR). Spontaneously, unanimously, the popular discontent has anointed the main opposition group with political and moral authority.

But these dissidents are not in any danger now from visionary fire-brands, and their entusiasm is strongly mixed with anxiety.

They know that if the authorities do not resolve quickly upon major political concessions, the extraordinary quiet explosion which has shaken Poland for 7 weeks could turn into tragedy. Everyone wants to believe that Soviet intervention is improbable, because of the fierce resistance it would encounter and because there is also the Afghan front. But everyone also knows that it could become possible, should the leadership, out of failure to take bold action, allow the chaotic wave of strikes to spread.

In Gdansk it is already a fact: the agitation for better social conditions has already taken a political turn. Just before last weekend began, management at the shipyards thinks it prudent to dismiss three agitating workers pre-emptively. Two of them, Mrs Anna Walentynowicz and Mr Nowicki, are old members of the 1970 strike committee. All three are linked to the opposition and participate in the editing of the opposition labor bulletin, ROBOTNIK ["The Worker"], which is widely disseminated in Gdansk. Time for discussing how to respond, to prepare statements, to make the roneos [translation unknown] turn, and the strike breaks out Thursday 14 August in the morning, after a distribution of tracts.

Three hundred people are going to demonstrate outside the management's offices, brandishing pennants: /"Restore the rolls," "Raise our wages!"/ A strike committee--10 people at first, 100 now--is formed. The movement spreads through the whole Lenin shipyard. Mrs Walentynowicz is reinstated by early afternoon. But there are 17,000 strikers, and negotiations must be begun. They will last until 0100, in the presence of the vovoide [translation unknown], and are followed by all the workers, broadcast direct by loud speakers.

A political theme--solidarity--lies at the orig'n of the movement: a political group played a decisive role in organizing it, but this is nothing beside the shock of the demands advanced.

In addition to wage increases (2,000 zlotys)*, retirement pensions and family allowances, the workers are also demanding the erection on the yard of a monument to the memory of the victims of the repression of December 1970 (several dozen deaths): the reinstatement of all persons discharged at that time; recognition of a representative trade union; the dissolution of the national directorate of the official trade union; the liberation of political prisoners; the closing fo the so-called /"commerc al"/ stores, whose prices are higher and which are getting more numerous; an audience with the prime minister; a pledge of impunity for the members of the strike committee, and finally, the publication of these demands in the press.

Friday at 0600 the management lets it be known that it is reconsidering the dismissals, that it agrees to the increase in family allowances to correspond, as demanded, with those for the police, a wage increase of 1,200 zlotys, that there will be no reprisals, and--what is unheard of--that the monument will be built to commemorate the 10th anniversary of December 1970. Activity and work must be resumed.

Not only is there no resumption, but the bus drivers in the city walk off, as well as [workers in] several other yards. The inhabitants are going to bring victuals and the results of their collections to the strikers who are occupying their place of work, and Gdansk (which suddenly cannot be reached by telephone) seemed, that evening, totally paralyzed.

Mr Babiuch's Intervention

Meanwhile, in Warsaw, Mr Gierek had returned in the morning, 24 hours early, from his Soviet vacation. An insistent rumor about an immediate convocation of the Political Bureau, followed by an important announcement, ran through the capital, and already theories are built up on the extent of the leadership shake-up. A shake-up which seemed indispensable and unavoidable to many officials. There was not (officially, at least)

---

* 1 zloty is worth about 13 centimes at official rates

a meeting of the Political Bureau, and no announcement. Only, after the televised evening news, a speech by the prime minister, Mr Edward Babiuch.

A strange, unreal sight: this small pudgy man, neuter and unexpressive, a portrait in shades of gray, reading carefully, seated, bent over under the Polish eagle, a long monotonous text whose only surprise was that it contained no surprise. Only mention of the aggravation of tension, /"the larger scale"/ of /"work stoppages"/ in Gdansk, and a moderate paragraph against /"enemies of people's Poland who are trying to profit from the atmosphere of tension and emotion for their [own] political ends."/

The rest of it was just everything is going badly but everything is all right. Everything is going badly in all sectors of the economy and in [availability] of supplies, and there is no miraculous remedy. The /"work stoppages"/, consequently, can only /"harm the interests"/ of the population, and the wage increases can only increase the deficit. We must work /"calmly, properly and with discipline"/ to solve the problems—which is not to impede discussion of the problems outside working hours and in a constructive and /"patriotic"/ spirit.

Everything is all right because /"I believe in the wisdom of the working class, in its class consciousness. I believe the working masses understand the exigencies of the state (...) and"/ (because) /"our common concern is the future of Poland."/ Four points more to raise: the government will present to the next plenary meeting of the Central Committee (at the end of September) /"detailed proposals"/ for resolving the economic crisis. Meat will not go up again between now and the fall of 1981. A very clear criticism of the former prime minister, Mr Jaroszewicz, relieved in February, who neither understand how to effectively head off the problems, nor warned the population. /"For many years,"/ he explained, /"we have spent more than we have produced, our national allocations have been greater than our national product, our national allocations have been greater than our national product, we have developed ourselves on credit."/ Today, /"Poland's level of indebtedness is such that it could not be further increased."/ And finally, one sentence: /"The world is watching us. We have loyal friends who are also concerned about our problems, who believe that we will be able to meet them alone, and who hope with all their hearts that we can."/

The general direction of his speech is clear: we know that you, the people, are sufficiently aware of the geo-political realities of the country to know not to go too far. It is therefore essential to wait for reason to prevail, not to dramatize the strikes, and to maintain the policy, adopted by the congress, of austerity and of very progressive mini-reforms.

It is a risky gamble. Economic recovery, for whatever reasons, will not meet expectations. And we will only be able to see in retrospect, tomorrow, or 6 months from now, whether it was not also playing with fire.

'We Will Hang On!'

Paris LE MONDE in French 17-18 Aug 80 p 2

[Text] Here is a report from AFP special correspondent Marian Kafarski, sent from Gdansk before telephonic communications were interrupted to the Baltic port.

After more than 30 hours of on-site striking, the atmosphere among the 16,000 workers in Gdansk's Lenin shipyards was one of determination.

Despite the discomfort and lack of sleep, the strikers are scarcely inclined to make the least concession. "We are steadfastly determined to continue with our action till our demands are met," we were told by Mrs Anna Walentynowicz, a member of the strike committee.

A heavy silence weighs over this place, usually swarming with life and resounding with the noises of sheet-steel working. The huge arms of the cranes are inert. The access gates to the shipyard are closed. Picketing strikers stand vigilant guard there and systematically empty every bottle of vodka contained in the baskets of provisions people have brought.

Before gate no 2, the same one where, in December 1970, the first strikers fell under fire from the army and the police, several hundred people have come to express their support for the workers. Mothers, wives have brought food for their son or husband. There is joking, smiling and mutual consoling.

The enormous grillwork gate is opened for the AFP representative, who is then amongst the strikers. Their expressions, unexpressive at first, brighten rapidly after introductions. The workers' responses are laconic. They can be summed up in one sentence: /"We will hold on!"/

In the immense conference hall of the shipyard, the strike committee is at full strength: about 100 people, compared with 20 at the beginning. The negotiations with management have been tough. They lasted until 0100 on Friday. The manager promised to resume with them at 0500. He has not yet come to the meeting. One hour later, he has made known his proposals: unacceptable, the strike committee answered, rejecting them out of hand.

The city of Gdansk is calm and quiet. The old city, moreover, has been paralyzed since Friday morning by a walk-out of public transport employees. In the streets, housewives hurry to do their shopping. The lines lengthen in front of the meat and pork shops, where smoked ham can be seen, a rather rare commodity. Immense waiting lines crowd around the bakers' shops overflowing [with people]. The deliveries didn't come? No, answers a cashier, people are stocking up provisions. Why? Instead of an answer, only a smile ....

In the sleeping city, no sign of police power. But the level-headedness of the angry workers and the inhabitants of Gdansk hides a worry that no one dares to express aloud. Everyone realizes that the situation is tense, as the grumbling of the workers at the shipyard has spread out over sister enterprises; the entire naval construction sector is affected by the strike. Work stoppages have hit ELMOR (electric installations), KLIMO (air conditioning), TECHMET (diverse installations) and OPAKOMET (metallic containers), among others. The workers at the North Yard (a new industrial port), for their part, had sent a delegation to their comrades in the Lenin shipyard.

'LE MONDE' COMMENTARY ON POLISH STRIKE, GEOPOLITICS NOTED

Paris LE MONDE in French 17-18 Aug 80 p 1

[Commentary]

[Text] The televised intervention of the Polish prime minister Friday evening is indicative of the disarray reigning in Warsaw: Mr Babiuch, in effect, has found nothing else to offer, in speaking to the strikers at Gdansk and elsewhere, than an indirect but perfectly clear allusion to an intervention by the Soviets, "our loyal friends, who are also concerned about our problems, who believe we will be able to meet them alone and who hope with all their hearts that we can ...."

History and geopolitics sometimes have implacable laws: thus the Polish authorities today have no other argument to offer the workers, whom in principle they represent, than the risk of intervention by the great protector of the socialist world. The argument, it is true, has carried some weight a few days from the 12th anniversary of the invasion of Czechoslovakia. However, at this point, there are no clear indications that this sinister scenario is going to be repeated. But the threat hovers overhead, even if the USSR, already entangled in Afghanistan, knows perfectly well that the Poles would not remain passive before an attempt at "normalization."

The labor crisis which is agitating Poland could not, however, have taken the leadership by surprise. After all, a similar crisis--though more violent--was what brought Mr Gierek's rise to power. If he is logical with himself, the Polish leader can only resort, once again, to negotiation. Did he not promise, right after the bloody repression of the Gdansk revolt of 1970, that never again would workers be fired on? We must hope that all the members of his team feel themselves equally bound by such a promise.

Other commitments, however, have not been kept. This is especially the case with the reform of the Polish labor apparatus, one of the questions which most stirs up the workers. Despite the revolts in Poznan, Gdansk, Ursus and Radom in 1976, which always started in factories and which

expressed the depth of the worker dissatisfaction with the absence of any forum of appeal, the communist government has not in any way modified the operation and the formal role of the trade unions. As in 1970, the latter are again headed by a veteran bereft of real power, Mr Kruczek, a survivor of the Gomulka era allied with Edward Gierek.

However, following the Baltic riots, voices made themselves heard not only in Poland, but also in the other countries of the East, such as Hungary and Romania, calling for a revision of the role of the trade unions. They were not heard, and as in the past, the trade unions are locked into the role of driving belt between the workers and the party. Which has generated the most explosive demand of the strikers of Gdansk, who demand the dissolution of the Central Council of Trade Unions and the creation of free unions.

This demand, which the strikers have apparently not abandoned, makes it impossible for the Polish leaders to continue to present the movement as purely "economic." This is what gives a new dimension to the crisis and puts Mr Gierek up against the wall. It is in effect practically impossible for him to defuse these "political" demands with "economic" concessions, however grave may be the country's situation on the economic plane: external indebtedness is breaking all records, energy costs—despite the increase in the price of coal—get heavier all the time, and the system of subsidization of food products, ruinous for the Polish state, is shown to be impossible to modify without bringing new protests.

LEADERSHIP'S ATTEMPTS TO SOLVE ECONOMIC PROBLEMS ANALYZED

London DZIENNIK POLSKI in Polish 9 Aug 80 p 4

[Article by Jozef Wroblon: "Who Will Guide Poland's Fortunes?"]

[Text] E. Babiuch Is in No Position to Undertake Economic Reform

In the wake of Stalin's death, one of the changes instituted in the ruling systems of Warsaw Pact countries was a repeal of the prohibition on obtaining loans from the West. Because Stalin was wary of Westerners even when they were offering dollar loans, he had forbidden Poland, among other countries, to partake of the benefits offered to it under the Marshall Plan. The relaxation of USSR-imposed discipline, continuing to this day, was used to advantage by E. Gierek who by June 1980 drove Poland's debt toward the Western countries to 19.5 billion dollars.

Unforeseen Consequence of Western Loans

Despite their considerable knowledge about Poland's political life, Americans, I believe, had not anticipated the far-reaching results caused by liberal granting of loans to a government incapable of putting them to proper use. Nothing seemed to indicate that an influx of funds, coupled with managerial ineptness, would cause the demotion of P. Jaroszewicz who as prime minister was responsible for the country's economic failure in 1971-80. This development was even more unexpected in view of the fact that P. Jaroszewicz enjoyed the trust of E. Gierek and his superiors, that is to say, he had proper "qualifications" for that post. A lack of trust was the undoing of by far more reasonable men like St. Olszowski and J. Szydlak who had the ambition and potential to correct P. Jaroszewicz's mistakes. They were doomed a long time before the PZPR Congress, whereas Jaroszewicz was only toppled by behind-the-scenes interventions of persons dissatisfied with the course of the congress.

Edward Babiuch's Program

This year's elected Sejm deputies listened in a session to a speech by Edward Gierek who presented an outline of Poland's social problems. It

dictated improvement of remuneration for efficient work and lowering of undeservedly high salaries. Further, it included providing support for families in difficult financial conditions and refinement of the principles permitting access to education, medical care and housing. Finally, Gierek[75] provided guidelines covering cadre-selection policies and employee promotion. It was nearly everything that seminar briefings at the Kremlin or in Crimea allow in the area of social issues. The extent of illusory correctness of these unrealistic directives is indicated, among other things, by the fact that even in 1978 a total of 42 percent of gainfully employed persons had earnings below the minimum of indispensable means of livelihood, and subsequent price increases drove them even lower down the scale of meeting their needs, as all of these people earned less than 4,000 zlotys a month.

Transposing those general directives onto problems that were closer to day-to-day life, Edward Babiuch had to accommodate the economic situation in his speech. It is generally known, however, that a prime minister is subject to no scrutiny in Poland. His only test comes in real life. This happens the sooner the more promising are his programs. Therefore, while E. Babiuch referred to price raises as one among the means leading to economic reform, these proved to be, after a few short months, the only item in his program that did not take long to be implemented.

Babiuch's expose gave top ranking to the problem of Poland's foreign debt, indicating the urgency of its reduction. The foreign trade deficit and substantial debt to hard-currency countries result, above all, from mistakes committed over a long period of time. It could be expected, therefore, that in his first speech Babiuch would give primary exposure to the origins of the economic disaster, rather than its consequences that are common knowledge. Before we deal with the tangibles that have remained of that speech, let us first survey its content in brief.

Next to Poland's foreign debt, the prime minister discussed shortfalls in market deliveries, persisting since 1945, though he recognized them as a novel phenomenon thus demonstrating in this regard a poorer grasp of matters of daily life than an ordinary man in the street. Subsequently, charges were leveled against agriculture because of its low output. Mention was also made of difficulties in the deliveries of crude oil and coal, raw materials and other materials, and of oversights in transport investments. Listed only at the end of this long tally of economic flaws were defects in the functioning of authority or, in common parlance, ineptness of ministers and bodies under their control.

The reasons that forced the prime minister to present a list of difficulties under which the entire economy is breaking down are profound and are certainly more serious than official communiques would seem to indicate. Their message is indeed one of "results in the black" but the truth can be actually described as nothing but a "black hole." Thus, it was officially announced that in 1979 the population purchased 73 billion zlotys' worth

less of needed articles than people sought to buy. It is a known fact, too, that what was purchased contained at least 10 percent of unnecessary or defective merchandise. In all, it was at least 16 percent less than the public's purchasing power. Imports surpassed the value of exports by $600 million. To this deficit, however, one should add repayment of debt and interest. Altogether they amount to more than $5 billion (repaid from successively incurred and increasingly expensive debts). Grain crops dropped down to levels indicated for 1974, that is, only 15.3 million tons were harvested. In effect, national income decreased 2 percent in relation to 1978.

These telling facts and figures forced E. Babiuch to advance a categorical demand that the plan for 1980 be seriously reduced. Although a decision to this effect by E. Gierek and a Sejm resolution are nothing but a mere confirmation of reports from the statistical office, at the same time, for the new prime minister, they are testimony that he "is not to blame" for the failures suffered up to now. It is doubtful if this is indeed the case. Although E. Babiuch did not sit in the government as Edward No 2, he had, approved, together with Gierek, governmental actions. The modifications enacted by the Sejm will decrease the foreign trade deficit. In the area of export and import alone, they represent a $900-million surplus of imports over exports, although additional loans will have to be obtained to repay the debt and interest. The list of disastrous failures should include woeful industrial performance wherein the costs (of materials) rose 79 percent while the value of (total) output increased a mere 57 billion zlotys. Hence revenue also dropped 61 billion zlotys.

A point of emphasis in Babiuch's speech that could be regarded as having some significance was the granting of various economic entitlements to both nonprivate and private agriculture, though verbalizations to that effect have for years lost all meaning to the Polish farmer. There is some validity bringing a measure of order into the convoluted mysteries of planning in Babiuch's statement indicating the need for putting central plans and local budgets in order. This was a hint addressed to T. Pyka, currently a vice premier in the government and former deputy chairman of the planning commission. His basic qualification for these posts was a close affinity with Gierek. During the period of his activity in the planning commission (after 1970), far-reaching disorganization was allowed in the functioning of this important area of control. Actually, E. Babiuch believes that enhancement of the importance of local plans is tantamount to greater democracy, but this is a topic we will leave aside for the time being.

A Step Ahead Or Into An Abyss?

The only item in E. Babiuch's program to see immediate implementation is the rise in prices for food articles designated for public supply.

It is known that in Poland meat or chocolate are in general as difficult to buy as furniture or atuomatic washers. Regardless of acute shortages

of virtually all articles of daily use, however, the prime minister assigned top urgency to regulation of government subsidies for diverse products totaling almost 500 billion annually, and an identical amount of surpluses obtained from other products.

It should be emphasized that those 500 billion zlotys constituted nearly 25 percent of (subdivided) national income per year, and as much as 45 percent in relation to the populations's consumption. It is beyond doubt, therefore, that dealing with a portion of the national income of this magnitude required extensive preparation, preliminary directives and reaching consensus with representatives of the people.

A preliminary analysis of surpluses and shortages in industrial production, farming and other national economic sectors indicates that the bulk of subsidies goes to first-order goods. Despite the institution of commercial prices, annual subsidies are over 67 billion zlotys for meat and meat products, 9.5 billion for fish, 36.4 billion for milk and milk products, 14.3 billion for sugar, and 15.3 billion for grain and grain products. This list should also include subsidies for agricultural supplies. If the latter were not applied, subsidies on first-order foods would have to mount. This group includes 15.7 billion zlotys worth of industrially processed feeds, 5.1 billion worth of artificial fertilizer, 3 billion worth of planting seed, and substantial expenses in assistance to purchase farm machinery.

Living standards of the population are contributorily improved by government-subsidized sales of coal and coke, furniture, and household appliances amounting to 5.8 billion zlotys, along with 79.6 billion zlotys channeled to assistance in communal economy, primarily transport equipment.

At this stage in our calculation, we have accounted for the allocation of 252 billion zlotys, that is, somewhat more than a half of the figure quoted by Babiuch. It can be assumed that approximately 50 billion zlotys are represented by other expenditures related with consumer supply and price supports for export-designated articles. This issue concerns the differences between prices paid for imported goods which were entered at lower cost in domestic industry plans, as well as facilitation of sales of Polish products abroad by way of price reduction.

Despite this, nearly 150 billion zlotys are unaccounted for in our very approximate calculation.

What Is Hiding at the Bottom of the Abyss?

I trust there is nobody in Poland to deny that goods with state subsidized prices include materials designated for military purposes as well. Babiuch's speech completely omits this matter, as has been the practice for 35 years. Yet it is clear that budget allocations for national defense cannot encompass such disbursements because they have to based on price lists that are

in force. It is true that from 1975 to 1978 the costs of national defense increased substantially from 47.6 billion to 59.7 billion zlotys. According to calculations conducted both in Poland and abroad, they amount to at least 20 percent of national income. Since (subdivided) national income for 1978 was over 1,965,000,000,000 zlotys, this means that approximately 390 billion zlotys are allocated to military expenditures. It is precisely this difference, that is 330 billion zlotys, that for many years has burdened the country's economy, and its overwhelming significance results from three causes.

First, it constitutes more than 15 percent of (subdivided) national income, which is why the claim about real expenditures on private consumption and investments are untrue. These are, in fact, 15 percent smaller than reported in official statistics. This is confirmed by examining private consumption and the state of investment in industry, construction, transport and farming.

Second, the national defense item of 390 billion zlotys accommodates 60 billion zlotys listed under budgetary expenditures and approximately 150 billion zlotys obtained from price subsidies, but the figure of 180 billion zlotys remains unexplained. It is (approximately) the amount the government has to extricate from diverse sources. Foremost of these is the placement of a substantial portion under investment expenditures in various economic sectors. This is done, for example, through decisions to grant apartments to persons employed by the army in buildings constructed by housing cooperatives; outlays for purchase of equipment indispensable for domestic completion of military production orders, and a host of ad hoc decisions resulting from varied and frequently unpredictable circumstances. This entire group of expenditures amounting to 330 billion zlotys (in 1978) is composed of a tremendous variety of decisions and, most important, it is funded from a great variety of sources, which is why the government has lost track of its size and, in effect, nobody is fully aware of its indispensability or logical justification. This loss of orientation is more detrimental to the economy than is the magnitude of these costs in itself.

Third, the country is suffering very grave damage because of confusion in production processes, confusion that stems from noneconomic pressures related with military-purpose deliveries. To begin with, an enterprise must fulfill its production plan for military items, for which it is accountable not only via its work force bonuses but through dismissal of its director as well. Furthermore, since such items are deficit, government-subsidized products, overfulfillment of the production plan is equivalent to deterioration of profitability (not in the financial aspect but because such products call for increased technological attention). For example, a steel mill manufactured "ground" fine steel rods for military purposes which are much more labor-intensive than "drawn" rods manufactured by the same steel mill to meet the needs of other clients. This fact, however, is in no way reflected in the price, though subsidized. Moreover,

preferential military orders reduce availability of productive capacities to other clients and diminish flexibility in modification of production processes to meet requests of domestic and foreign customers. When reorganizing the system of economic management, the government must at all times respect the inviolability of military deliveries in terms of their composition, quality, quantity and prompt completion. These circumstances appreciably increase production costs (due to difficulties in securing supplies of raw materials and other materials). This happens especially in cases where hard-currency imports must be substituted for promised domestic deliveries.

In order to remove these obstacles to even the slightest improvement of the economy, prices of military-purpose deliveries should simply be based on levels dictated by manufacturing costs. Further, to secure financial resources for all kinds of military purposes, budgetary expenditure figures for national defense should be raised. It would be demonstrated then, however, that they represent approximately 20 percent, not 3 percent, of (subdivided) national income. It is obvious that this cannot be consented to by an alliance of countries that allocates sums equivalent to what the Red Cross collects in a street fund raiser as their assistance to starving nations.

"De Profundis Clamavi"

What is going on in Poland now can be called a cry from the depth of despair of the rulers who do not want to lose their positions and the people faced with either extreme poverty or the risk of a bloody uprising. In this situation, it is exceedingly difficult to maintain equilibrium for the government, and even more so for those governed.

Consequently, Babiuch's activity began with measures calculated to buttress his own image. First, using resignation from his post as leverage, he obtained E. Gierek's approval, along with a formal act of the Sejm, to trim the recently enacted industrial production growth plan in 1980 from 3-4 percent down to 2-3 percent together with reduction of profit in the entire economy. On the other hand, export figures were raised (and import deliveries were cut down), with a corresponding deterioration of domestic supply. Next, E. Babiuch persuaded the first secretary of the PZPR to be the one, rather than Babiuch himself, to explain the country's economic calamity in front of TV cameras. Yet these two facts demonstrate only good strategy of E. Babiuch as a party activist, not his qualifications as an economic manager. In the course of his TV appearance, E. Gierek informed the public that a salary reduction was inevitable, while the minister of agriculture on his part announced substantially smaller grain crops than in 1979. The minister of domestic trade also participated in this TV appearance in order to take the blame for reduction of deliveries of goods for the population's needs. The fourth participant, a minister of foreign trade, was the only one to state improvement in the results of foreign trade with hard-currency countries during the first 6 months of 1980, amounting to $200 million.

He made no mention, however, of the lack of resources to pay interest on the incurred loans and to repay debt inatallments.

Following these tactical preparatory moves, the prime minister took action. Early on, however, he immediately made two errors. First, price rises were initiated without an evaluation of their consequences for working people and without factual evidence that they would involve increases in earnings. The public showed restraint in their assessment of the situation so long as higher pricing concerned newspapers, cigarettes, sewing machines, automatic washers, refrigerators and apartments. People flew into a passion only when meat disappeared from lower-priced general supply stores and became available in greater quantities in commercial stores (at higher prices). Strikes in industrial facilities and in the transport sector sent a tremor through Ursus, Warsaw, Tczew, Swidnik, Lublin and many other cities, including even the principal armament installation of Stalowa Wola. Under the impact of these self-protective actions social awareness of the economic situation increased along with a will to resist the authorities' inept decisions. In an attempt to escape at least a measure of responsibility, the government announced that delayed notification about changes in the sales system and price increases resulted from the oversight of accountable officials.

Numerous circumstances indicate that:

--the government will not undertake (as it did not for 35 years) any essential economic reforms, limiting itself to certain administrative decisions that may include price changes or reorganization of enterprises, industrial associations or even ministries; at the same time, however, there will be growing indignation and bitterness in the nation, enveloping new areas of the country and reinforcing the belief that PZPR-designated authorities are incapable of improving the economic situation;

--it is not possible to govern a country whose population is deprived of representation even through trade unions, while a bureaucratic apparatus claiming that name has at its disposal neither a substantive and comprehensive analysis of the standard of living of the working people, nor a calculation of their future needs, in other works, family budgets.

Another decade has passed, and the compelling question that emerges from the chaos is whether the country's future will be guided by an authority handpicked outside its borders, or whether the government will become a democratic representation of society composed of outstanding specialists selected on the basis of comprehensive evaluation of their qualifications.

BRIEFS

ELECTRIC POWER REQUIREMENTS, PLANS--Investments are obviously important for the construction of certain installations, for example, at Belchatow or Polaniec. Delays are occurring, and an additional power output of 1,680 MW is required in 1980 in order to strengthen the power system. In the next 1981-1985 plan, power equipment providing approximately 11,000 MW and heat generating systems having an output of 11,600 giga-calories per hour will have to be put into operation in the electric-power and power-heat generating plants of the public-utility type. In addition, power facilities, primarily transformer stations having a power rating of 36,000 MVA, and approximately 46,000 transmission and distribution lines in the power networks will have to be put into operation. AMENDED LAW ON ANIMAL RAISING PUBLISHED

Bucharest BULETINUL OFICIAL in Romanian Part I No 57, 9 Jul 80 pp 1-8

[Law No 40/1975 on the Raising and Improvement of Animals]

[Text] Law No 40/1975
on the Raising and Improvement of Animals*

In the Socialist Republic of Romania, animal husbandry represents an activity of national interest, it having a leading role in supplying to the population meat, milk, eggs and other products of animal origin and to industry raw materials needed to increase the production of consumer goods.

The erection of the multilaterally developed socialist society in our country and the continual raising of the standard of living and the consumption capacity of the population necessitate the raising of zootechny's percentage in agricultural production, through the raising of the populations of animals, the improvement of their productive potential and the improvement of the technologies for efficiently exploiting and utilizing all fodder resources.

For attaining these objectives, the state creates conditions for continual development of animal husbandry, both in the socialist agricultural units and on the population's farms, by allocating large amounts of investment funds for the construction of new zootechnical facilities, by granting loans for the procurement of animals, by staffing the units with specialized personnel, by organizing units specializing in the production of reproductive material, by importing animals from improved breeds and by establishing stimulative prices for animal production and for reproducers with high genetic potential.

---

* Republished on the basis of Article II of State Council Decree No 184 of 11 June 1980, published in BULETINUL OFICIAL AL REPUBLICII SOCIALISTE ROMANIA, Part I, No 46, 13 June 1980, with a new numbering being given to the articles.

Law No 40/1975 was published in BULETINUL OFICIAL, No 134, 25 December 1975.

In order to fully utilize the soil, climatic, social and economic conditions existing in different zones of the country, the Ministry of Agriculture and the Food Industry, together with the people's councils, organizes zootechnical production on a territorial basis and is responsible for the achievement of animal production.

For the further development of animal husbandry, the Academy of Agricultural and Silvicultural Sciences, through the specialized research units and the institutes of agronomic higher education, participates in the activity of devising and applying the most efficient methodologies of breed improvement, in the expansion of the use of improved reproductive material in the production units, and in the improvement of the husbandry technologies and is responsible for their application and implementation according to the zones and the groups of units that are assigned to them.

The creation of a unified legal framework regarding the raising, improvement and reproduction of animals is required in order to fulfill these tacks.

To this end, the Grand National Assembly of the Socialist Republic of Romania adopts the present law.

Chapter I
Animal Husbandry

Article 1. Animal husbandry is an activity of national interest and has as a goal the supplying of the population at the level of the growing consumption requirements and the meeting of industry's needs for raw material with products of animal origin.

The development of animal husbandry is achieved in accordance with the National Program for Development of Zootechny and Growth in Animal Production, whose provisions are binding on all possessors of animals.

Article 2. For the development of animal husbandry, the establishment of the percentage of the species according to geographical and administrative zones, and the selection of the breeds and of the systems of raising and exploitation, the Ministry of Agriculture and the Food Industry and the executive committees of the county people's councils and that of the municipality of Bucharest will provide for the better utilization of pastures and hayfields, especially those in hilly and mountain zones, and of all fodder resources in agriculture, the food industry and other activities of the economy.

Article 3. In order to continually improve the population's supply of animal products and avoid the expenses caused by the transportation of products over long distances, the Ministry of Agriculture and the Food Industry, together with the people's councils, will provide in each county the conditions needed to develop animal husbandry, which should meet its own consumption needs and achieve the reserves arranged by means of the plan.

Article 4. In socialist agriculture, benefiting from the multilateral support of the state, the development of animal husbandry will be oriented further toward the concentration, specialization and integration of production and will be achieved through the construction of new, rationally dimensioned units and the modernization of the existing ones.

Article 5. The socialist agricultural units have the obligation to keep the animal shelters, the outbuildings and the technical resources on hand in optimum condition, in conformity with the technical instructions, and to keep the technical equipment in permanent operating condition.

The changing of the purpose of the zootechnical constructions or the resources on hand is permitted only with the approval of the higher-ranking body.

Zootechnical constructions with a value of over 200,000 lei cannot be removed from the animal production circuit except with the approval of the Ministry of Agriculture and the Food Industry.

Article 6. The state supports the development of animal husbandry on the population's farms, providing:

Reproducers, through the communal mating stations;

Seminal material and technical assistance for artificial insemination in animals, free of charge;

Technical assistance and financial resources for the improvement and arrangement of natural meadows, in order to increase the fodder resources;

The right to use, on easy terms, state-owned pastures and hayfields, as well as pasturable forests, in accordance with the legal provisions;

Some assortments of fodder for the animals and products contracted for with the state, under the conditions provided by law;

The awarding of bonuses for each heifer at the first calving;

Technical advice through personnel with specialized training, veterinary assistance, and medicine for veterinary use;

Loans, on easy terms for raisers, in order to procure production animals.

The population in villages and cities can buy or take over on a contractual basis from the socialist agricultural units animals and poultry for raising and fattening.

Article 7. For raising the contribution of the population's farms to increasing the vegetable and animal agricultural production and meeting their

own consumption needs with meat and other animal products, all inhabitants in rural and urban areas who possess farmland are obligated to cultivate it and to raise animals and poultry.

The farmland cannot be possessed except by the physical persons who cultivate it and raise animals and poultry, under the conditions provided by law.

The vegetable and animal production obtained on the population's farms will be used for the food needs of the producers and their family members, and the extra quantities will be able to be utilized, under the conditions provided by law, on the market or through contracting and purchases for the state supply.

Article 8. The executive committees and bureaus of the people's councils are responsible for the complete and efficient use of farmland, for the fulfillment of the plan for populations of animals and poultry on the population's farms, for the creation of the resources of animal products needed to meet the needs of the own consumption of the population in their range of activity, and for the fulfillment of the plan targets for contracting for and delivering to the state supply animals, poultry, milk, eggs and other animal products.

Article 9. The executive committees of the county people's councils and that of the municipality of Bucharest will assign and transmit annually to the executive bureaus and committees of the communal, city and municipal people's councils the plan indicators concerning the populations of animals that must be raised by the population's farms.

On the basis of the plan targets received, the executive bureaus and committees of the communal, city and municipal people's councils will draw up animal- and poultry-raising programs for each farm in territorial-administrative range, so that each can fulfill the obligation to raise animals and poultry.

The number of animals and poultry that can be raised by each farm for its own needs, for sale on the market or for contracting or purchases is unlimited.

The executive bureaus and committees of the communal, city and municipal people's councils will include in the programs concrete targets for each farm, on the basis of wide consultation with the citizens, establishing the number of animals and poultry, the production and the deliveries to the state supply, in correlation with the targets for economic and social development of the territorial-administrative unit. Targets for cultivating all areas and planting fruit trees and bushes, the agricultural output that will be obtained and the deliveries of vegetables, potatoes, fruit and other produce to the state supply will also be established accordingly.

The programs for developing the populations of animals and poultry are subjected to discussion by the general assemblies of the inhabitants in communes and become binding on all inhabitants in rural areas, after their adoption by the people's councils.

Article 10. The executive bureaus and committees of the people's councils will give the population's farms the support needed to develop their production base and will seek to provide the conditions needed to fulfill the tasks assigned to them, for increasing the vegetable and animal agricultural production and achieving the deliveries to the state supply.

To this end, the executive bureaus and committees of the people's councils will take the following steps:

a) The land in the possession or use of the inhabitants and that under the administration of the executive bureaus or committees of the people's councils will be cultivated completely with vegetables and potatoes, planted with fruit trees and bushes and cultivated with fodder plants or other farm crops, in accordance with the programs established;

b) The natural meadows administered by the executive bureaus and committees of the people's councils and the pasturable land in the forest reserves will be allocated, according to law, with priority to citizens who contract to deliver animals and animal products to the state supply.

The members of the agricultural production cooperatives, besides the measures stipulated in the preceding paragraph, benefit from facilities established by the general assembly of the agricultural cooperative, such as:

a) The granting of roughage and of land areas, for fodder production in the catch crop, with priority to contractors for animals and animal products;

b) The allotting of areas of hayfields, for harvesting with payment in kind, only to contractors for herbivores or for animal products from them.

Article 11. Distinct targets for the raising of piglets and chicks, which are to be sold to the animal raisers who contract to deliver animals, animal products and poultry to the state supply, will be established, within the framework of the plan, for the socialist agricultural units.

The socialist agricultural units are authorized to organize, beyond their plan targets, the production of chicks, piglets and rabbits that they may turn over, together with some quantities of fodder for raising and fattening, on a contractual basis, to producers on the population's farms that have conditions of space and certain possibilities of feeding and possess the necessary manpower.

The payment for the work of the producers will be made to the account of the respective agricultural unit on the basis of the rates established for

the weight of the fattened or raised animals that have been delivered to the state supply, at the weights stipulated by means of the contract.

Article 12. The units of the consumer cooperative system will participate in the fulfillment of the targets for increasing the populations of animals on the population's farms, through the organization of stock farms for sows and day-old chicks, in order to obtain products that may be sold to the animal raisers.

Article 13. The Ministry of Agriculture and the Food Industry, the National Union of Agricultural Production Cooperatives and the Committee for Problems of the People's Councils will take the steps needed to provide the population's farms with seeds and planting stock, with chemical fertilizer, with purebred animals for mating and with zooveterinary assistance. In addition, they will create possibilities of the rental or purchase of farm implements and animal-drawn agricultural machines by the population's farms and will provide service with tractors and agricultural machines for the mechanized performance of the necessary work on the land used by these farms.

Article 14. The socialist units within which cafeterias operate, the public food units, the tourist chalets and other such units are obligated to organize subsidiary activities for raising animals and poultry, through the utilization of all food scraps and other available resources, for meeting their own needs, within the established consumption quotas, and for utilizing the surplus for the state supply.

Article 15. In order to provide the population's farms with animals for raising and fattening, the Ministry of Agriculture and the Food Industry, together with the people's councils, will take steps to increase the breeding stock on these farms. To the same end, they will support the organization of the production of piglets, chicks and other species and categories of animals, both within the population's farms and within the animal-husbandry associations or through the consumer cooperatives in the locality.

The people's councils and the agricultural bodies will support the founding of the animal-husbandry associations and the organization by them of the actions connected with the improvement of livestock, the raising of animal production, the improvement and use of meadows, the mechanization of work in zootechny, the guarding of the health of the animals and the protection of them, and the contracting for and the sale of the production.

Article 16. In order to meet the need for fodder for the animals possessed by the socialist units and the population's farms, the Ministry of Agriculture and the Food Industry, together with the people's councils, will organize the production of fodder, will provide for the development of the material base for the production of mixed feed and will keep track of the manner of conservation and use of all fodder resources, in conformity with the standards in force.

Article 17. The Ministry of Agriculture and the Food Industry will draw up technical standards for raising and exploiting the animals, varying according to systems of raising, according to geographical zones and according to forms of ownership, based on the results obtained by the specialized research units. These standards are binding both on the socialist agricultural units and on the population's farms.

Chapter II
The Improvement of Animals

Article 18. The improvement of livestock, in the sense of increasing the genetic potential, is achieved on the basis of the improvement programs drawn up by the Ministry of Agriculture and the Food Industry. The methodology of selection, the husbandry technology, the volume of activity and the organizational framework for the production, quality control, and use of the reproductive material from each species of animal are established by means of these programs.

The production and use of reproductive material are achieved within the framework of the program for zoning of animal husbandry and have as a goal the fulfillment of the annual and long-term plans.

Article 19. By "reproductive material," in the sense of the present law, is meant:

a) The male reproducers and the young males kept for verifying their own performances;

b) The young males and females kept for testing the parents or collateral relatives from the cattle, swine, sheep, goat, horse, rabbit and furred-animal species;

c) The females from the cattle species, in their entirety, and the females from the swine, sheep, goat, bubaline, horse, rabbit and furred-animal species contained in the breeding records and approved on the basis of certificates of quality;

d) The lines and nuclei of certified poultry, as well as the eggs for incubation and the day-old chicks that have been obtained from these lines or from combinations of lines selected for the production of hybrids;

e) The nuclei of animals and poultry utilized for the creation of new breeds, types, lines or hybrids;

f) The seminal material used in artificial insemination and the zygotes utilized in the work of transplantation.

Article 20. For the production, quality control, and use of the reproductive material for animals, the Ministry of Agriculture and the Food

Industry, through its specialized bodies, bears the responsibility and provides for:

a) The organization and operation of the units that produce reproductive material, by continually concentrating the elite animals in order to form nuclei of the greatest zootechnical value;

b) The organization and operation of the units and work points at which the testing of the animals that are selected for maintaining and improving the elite nuclei and for providing reproducers for the rest of the livestock is done, on the basis of their own performances and the offspring;

c) The production of the assortments of feed necessary to the units at which work of testing and selection is done, in accordance with the formulas required by their technology, in order to correctly determine the genetic potential, and the organization of the production of fodder for the rest of the livestock, at the level required by their productive potential;

d) The inclusion of the livestock needed to achieve the improvement work, from the best nuclei of animals existing at the socialist agricultural units and on the population's farms, in the official production inspection, in order to know the productive capacity of the animals and identify the most valuable specimens;

e) The guaranteeing by the state of the zootechnical quality of the reproductive material, noted in certificates of quality issued after the official production inspection;

f) The recording of the specimens that, through the value of their performances, can contribute to the improvement of the breeds in the state genealogical registers;

g) The management of the supply of reproducers and the reproductive material, through the controlled allocation of them, for satisfying the requirements in all zones and systems of animal husbandry;

h) The importation of animals, poultry, eggs and seminal material from the improved breeds and types that can be utilized under the climatic and technical operating conditions of the production units in our country, with the guaranteeing by the exporters of their indemnity for specific contagious diseases;

i) The guarding of the health of the livestock subjected to selection through the continual providing of preventive and curative health and veterinary assistance, given by the own veterinary personnel of the units that possess them or of the health and veterinary districts.

Article 21. The Academy of Agricultural and Silvicultural Sciences, through the subordinate specialized research units, has the obligation and bears the responsibility regarding:

a) The continual perfecting of the methods of improvement and of the programs or instructions for applying them;

b) The management of the work of creating new breeds, types, lines or hybrids of animals and poultry;

c) The guidance of the work of studying the adaptive capacity of imported reproductive material and the establishment of the method of using it in the animal-improvement process;

d) The devising and the pursuit of the application of new animal-raising and -exploiting technologies;

e) The production and furnishing of reproductive material with a high genetic value, from its own units possessing animals.

Article 22. The organization, management, coordination and guidance of the actions of producing and using the reproductive material for animals are in the charge of the Ministry of Agriculture and the Food Industry and are achieved through specialized units that have as an object:

a) The production, raising and maintenance of the reproductive animals with a role in improving the livestock;

b) The testing of reproductive material on the basis of its own performances or on the basis of offspring;

c) The multiplication of the selected animals by means of pure breeding or by means of crossbreeding;

d) The production, preservation and furnishing of the seminal material for artificial insemination or of the zygotes used in the work of transplantation.

Article 23. In order to determine the productive potential of the animals in the specialized units, stipulated in Article 22, the feeding will be done in accordance with scientifically substantiated standards, diets and formulas devised by the specialized research units, approved by the Ministry of Agriculture and the Food Industry and applied only in the units with this type of activity.

Article 24. The Ministry of Agriculture and the Food Industry organizes, manages and guides the work of judging and certifying the quality of the reproductive material for animals, through the units that have as an object of activity the performance of the official production inspection.

The reproduction and selection units also have the task of guiding and supervising the way in which the use of the selected reproductive material is done in the production units and of providing for its dissemination and pursuing its reproduction.

For ensuring the accurate processing of the data resulting from the production inspection and for increasing the effectiveness in making the decisions on selection, the national reproduction and selection unit will organize the automatic data-processing system.

The official production inspection refers to the recording of the performances of the animals subjected to selection and to the respecting of the conditions of maintenance, feeding and care in the units that produce, test or receive for use improved reproductive material.

Article 25. The quality of reproductive material and its value are confirmed by means of certificates of origin and productivity issued by the county reproduction and selection unit that performs the production inspection for animals.

Certificates will not be issued except for the animals that are registered by means of numbers or codes applied directly on a part of the body or by means of standardized ear tags.

The system of registering the animals and marking the other reproductive material is established by the Ministry of Agriculture and the Food Industry.

Article 26. Pure breeding will be used as a chief method for improving the livestock.

The multiplication of the animals stipulated in Article 20, letters a and f, will be done only by means of pure breeding.

The work of crossbreeding and hybridization, done in order to increase the productive capacity of the animals and poultry in the production units, will be achieved in a controlled fashion, with the technical support and under the guidance of the units that perform the official production inspection, on the basis of scientifically substantiated programs drawn up through the Academy of Agricultural and Silvicultural Sciences by the specialized research units and approved by the Ministry of Agriculture and the Food Industry.

Article 27. The male reproducers—bulls, boars, rams and stallions—used at the units that produce seminal material and at the communal mating stations and points and the entire populations of animals in the units included in the provisions of Article 22, letters a and c, are subjected annually to evaluation and classification.

The organization and performance of the work of evaluation, the technical standards and the methodology for judging the reproductive material will be established by the Ministry of Agriculture and the Food Industry.

For verifying the origin of the reproducers and the quality and healthiness of the seminal material and for judging the production of the animals

subjected to the official inspection, the national reproduction and selection unit will found, with the approval of the Ministry of Agriculture and the Food Industry, its own laboratories, which will also function as laboratories for expert evaluation.

Article 28. The approval of the new breeds, types, lines and hybrids of animals, poultry, bees and silkworms that are achieved in the research and production units and by the population's farms is done by the Ministry of Agriculture and the Food Industry, on the basis of the conclusions drawn from the analysis of the results obtained in the verification work advised by the Zooveterinary Council.

The verification work is organized in centers for approval of the performances of animals by the units that perform the official production inspection and is done under the conditions established by means of verification protocols drawn up together with the specialized central research unit, it extending over at least two successive generations.

In the case in which it is considered necessary, nuclei of animals from the imported breeds or those that are intended to be imported are also subjected to the same verification.

Article 29. In order to recognize and popularize the socialist agricultural units and the raisers that distinguish themselves in the activity of raising livestock of great zootechnical value and in using a modern technology of exploitation, the Ministry of Agriculture and the Food Industry and the executive committees of the county people's councils and that of the municipality of Bucharest will annually organize animal and poultry fairs with the establishment of the county, zonal and national champions of the breed and with the awarding of incentives in money, objects and certificates, within the limits of the funds that have been allocated to them for this purpose.

Chapter III
The Organization of the Reproduction of Animals

Article 30. The activity of reproduction of animals has as a chief objective the rational use of the breeding stock and the young breeding stock, the continual raising of the birth rate and the obtaining of more valuable products that express the improved genetic potential as a result of the improvement work done.

Article 31. For performing the tasks stated in Article 30, annual indicators of birth rate according to species of animals and according to counties will be established in the sole national plan for economic and social development.

On the basis of these indicators, the managements of the socialist units will prepare, with the technical assistance of the reproduction and

selection units, mating and birthing plans for the animals belonging to these units.

For the animals on the population's farms, the mating and birthing plan is prepared by the local specialized personnel, together with the possessors of animals.

Article 32. Male reproducers can be used only after authorization.

The authorization of the use of male reproducers is done, for natural mating, by the county unit and, for artificial insemination, by the national unit that performs the official production inspection.

The reproducers reaching mating age for which use has not been authorized are subjected to sterilization.

Article 33. The production of reproductive material is provided as follows:

a) The male reproducers and the young males meant for testing their own performances will be produced by the units stipulated in Article 22, letters a, b and c, and by other socialist units or by the population's farms, from the animals included in the official production inspection, by means of listed pairings;

b) The young males and females needed for testing the parents or collateral relatives will be produced by means of controlled pairings, both in socialist agricultural units and on the population's farms, on the basis of the contract concluded with the units within which work of testing is organized, with the possessors having the obligation to furnish them on the agreed date and under the agreed conditions;

c) The female reproductive material from the cattle species will be produced in the socialist agricultural units and on the individual farms from their own breeding, and the female reproductive material from other species, stipulated in Article 19, Letter c, is produced in the socialist agricultural units or on the population's farms from animals included in the official production inspection;

d) The calves will be retained in their entirety and raised for reproduction.

The cow-raising zootechnical units will take steps to provide, within the existing space, sectors for separately raising and tending the bull calves and the heifers until mating.

Mating with suitable breeds, specific to the respective zone, will be provided for all heifers, and the selection of them for reproduction or for culling will be done only after calving in relation to the results obtained in the first production cycle.

In wholly special cases, due to incurable diseases that make them unfit for reproduction, the calves will be able to be butchered only with the approval of the health and veterinary inspectorate;

e) The selected lines of poultry, the eggs for incubation and the day-old chicks will be produced by the poultry-breeding units and by the population's farms, members of the association of breeders, with the authorization of the unit that performs the official production inspection;

f) The nuclei used to create new breeds, types or lines are formed in scientific research units and, by way of exception, in other agricultural units or on the population's farms, under the control and guidance of the specialized research unit under the Academy of Agricultural and Silvicultural Sciences;

g) The seminal material for artificial insemination will be produced as follows:

Frozen seminal material and zygotes for transplantation, in the specialized units authorized by the Ministry of Agriculture and the Food Industry;

Refrigerated and fresh seminal material, until its replacement with frozen seminal material, in the county reproduction and selection units or in subunits for artificial insemination;

Seminal material for experimental work, in research units, on the basis of the annual plan of subjects.

The seminal material is furnished or is disseminated along with a waybill, issued by the producing unit, that confirms its origin and quality.

Article 34. The activity of reproduction by means of artificial insemination is organized by the county reproduction and selection units or by state agricultural units, which are responsible for the proper operation of the artificial-insemination points in their range of activity.

The operations regarding artificial insemination will be performed by livestock experts and veterinarians, who are responsible for the results of this work. Until the need for such personnel is met, other, specially instructed personnel can also be utilized to perform this activity, under the same conditions of responsibility.

The right to perform artificial insemination is given on the basis of a permit issued by the county reproduction and selection units.

In the state agricultural units and in the agricultural production cooperatives, the farm foreman is responsible for the activity of reproduction and artificial insemination. The veterinarians and specialized personnel who perform artificial insemination are responsible for the fulfillment of the mating and birthing plan for the animals on the population's farms.

Article 35. In the localities in which artificial insemination of animals is not practiced for one or more species, the executive bureaus or committees, respectively, of the communal, city and municipal people's councils will organize communal mating stations, under the guidance of the local personnel with zootechnical or veterinary training who have in their responsibility the mating and birthing plan for the animals on the population's farms.

In the localities in which the stock of cattle, sheep, goats, horses and swine for organizing a communal mating station is not congregated, including the localities in which agricultural production cooperatives are organized, when their situation requires it, the executive bureaus or committees, respectively, of the communal, city or municipal people's councils will set up mating points, with state-owned reproducers or with authorized reproducers that belong to the population's farms.

Article 36. The use of reproductive material and its multiplication in the production units in order to increase the populations of improved animals are done in conformity with the reproduction program prepared by the Ministry of Agriculture and the Food Industry, on the basis of a uniform methodology, in accordance with each system of reproduction and each species of animal.

Article 37. The Ministry of Agriculture and the Food Industry, the executive committees of the county people's councils and that of the municipality of Bucharest, and all possessors of animals have the obligation to provide for the normal process of reproduction, for all species of animals, with high-quality reproducers, in accordance with the established standards.

The allocation of reproducers for the production of frozen or refrigerated seminal material and for natural mating is done annually by the Ministry of Agriculture and the Food Industry, at the proposal of the national reproduction and selection unit, on the basis of the need established on the occasion of the work of evaluation.

Article 38. The reproducers from the cattle, sheep, swine and horse species will be procured exclusively from the breeds stipulated on the zoning map and only from the units subjected to the official production inspection.

The furnishing of male reproducers is done with the technical assistance of the county reproduction and selection unit in whose range the supplying unit is found. The reproducers furnished will be accompanied by certificates of origin and productivity and by health and veterinary certificates.

Article 39. The financial resources needed for the procurement of reproductive animals are formed, for the state agricultural units, from their own circulating funds and, at the other specialized units and at the people's councils, from the investment funds.

In the cooperative agricultural units, the reproductive material is procured from their own development fund and from long-term loans, in conformity with the legal standards in force.

The seminal material, including zygotes, produced in the units that process frozen seminal material is furnished at cost to the purchasing units.

The reproduction and selection units pay for seminal material from budgetary funds under the conditions and at the prices that will be established by the Ministry of Agriculture and the Food Industry, with the advice of the Ministry of Finance, and disseminate it free of charge to the agricultural production cooperatives, the intercooperative economic associations and the population's farms.

Article 40. The male reproducers from the cattle species tested on the basis of offspring are treated as fixed assets and are excepted from amortization. In addition, the other reproductive animals treated as fixed assets, from the specialized units subordinate to the Ministry of Agriculture and the Food Industry and from the people's councils, are not amortized.

Article 41. In order to know at any time, according to breeds, the number and the quality of the reproducers in the artificial-insemination or natural-mating units and in the other socialist units, as well as the right to use them, the record of reproducers will be kept nominally as follows:

a) The national reproduction and selection unit will keep the record of imported bulls, stallions and rams, of those used in the production of frozen seminal material, and of those in the county reproduction and selection units, with the possessing units being obligated to report on the inclusion and exclusion of reproducers;

b) The county reproduction and selection units will keep the record of the state-owned reproducers, procured from the funds allocated to the counties, that they have under administration and of the other reproducers authorized for mating, regardless of ownership;

c) The socialist agricultural units and the executive bureaus or committees, respectively, of the communal, city and municipal people's councils will keep the record of the reproducers on hand or allocated for temporary use.

Article 42. The specialized technical bodies, the socialist agricultural units and the population's farms are obligated to keep, in conformity with the technical standards drawn up by the Ministry of Agriculture and the Food Industry, the pedigreed male and female reproducers in conditions that ensure high fecundity and prolificacy and the prevention of miscarriages, of losses of pregnant animals, and of mortality in birthing or after birthing and to record and report the results obtained.

The veterinarians and experts in the units are obligated to take steps to prevent and treat reproductive disorders in animals and to perform the diagnosis of gestation, in conformity with the rules established by the Ministry of Agriculture and the Food Industry.

Article 43. The Ministry of Agriculture and the Food Industry, together with the Ministry of the Chemical Industry and the other central bodies with tasks in providing for the production of preparations and medicine for veterinary use, will take steps to continually meet from domestic production the need for biological and medicinal products for preventing and combating reproductive disorders in animals.

The treatment of reproductive disorders in the cattle in the cooperative agricultural units and on the population's farms is done free of charge.

Chapter IV
Responsibilities and Penalties

Article 44. The violation of the provisions of the present law results in disciplinary, material, civil, contraventional or penal responsibility, as the case may be.

Article 45. The following constitute infractions:

a) The production of frozen seminal material outside the authorized units or from the reproducers for whose use permits have not been issued;

b) The dissemination of the seminal material produced outside the authorized units or from the reproducers for whose use permits have not been issued;

c) The act of disseminating out of fault the seminal material produced under the conditions stipulated in Letter b.

The infractions stipulated in letters a and b are punishable with imprisonment from 6 months to 5 years.

The infraction stipulated in Letter c is punishable with imprisonment from 1 month to 2 years or with a fine.

Article 46. The declaration of untrue data regarding the origin, age, productive performances, or state of health of reproductive material constitutes an infraction and is punishable with imprisonment from 3 months to 2 years or with a fine.

Article 47. The performance of artificial insemination by unauthorized persons constitutes the infraction of practicing a profession without the right and is punishable in conformity with Article 281 of the Penal Code.

Article 48. The following acts constitute contraventions to the provisions of the present law, if they are not committed under such conditions that, according to criminal law, they constitute an infraction:

a) The refusal to perform the animal-husbandry tasks established by the people's councils in accordance with Article 9;

b) The failure to comply with the technical standards with regard to numerically providing the male reproducers used in natural mating, in accordance with the established number of females;

c) The failure to comply with the plan of listed pairings, the depreciation of reproductive material, the unauthorized alienation of it or the butchering of it that cannot be justified by means of the health and veterinary certificate;

d) The use of unauthorized males for mating with females;

e) The changing of the purpose of zootechnical constructions in violation of the provisions of Article 5, paragraphs 2 and 3;

f) The preservation of seminal material or of eggs for incubation under conditions that cause their depreciation;

g) The failure to provide for individualization or the individualization that creates doubts about the identity of the animals subjected to the official inspection, of the animals used in the work of testing the male reproducers, and of seminal material or of eggs for incubation;

h) The act of entering, out of fault, erroneous data regarding the origin, age, productive performances and indices of quality of seminal material or the state of health of reproductive material in the zootechnical record, in the certificates concerning the quality of reproductive material, or in the veterinary certificates;

i) The use of unauthorized males as reproducers for mating or the refusal to sterilize them.

Article 49. The contraventions stipulated in Article 48 are penalized as follows:

The contraventions stipulated in letters a, b, c and d, with a fine from 300 to 1,500 lei;

The contraventions stipulated in letters e, f, g and h, with a fine from 1,000 to 3,000 lei;

The contravention stipulated in Letter i, with a fine from 1,000 to 3,000 lei and confiscation of the animal.

The contraventional penalites can also be applied to legal persons. The fines applied to legal persons will be charged by them to the physical persons at fault.

Article 50. The ascertainment of contraventions and the application of penalties are done by representatives of the minister of agriculture and the food industry, in the central apparatus of the ministry, in the reproduction and selection units and in the apparatus of the county agricultural bodies and that of the municipality of Bucharest, and by mayors.

Article 51. The provisions of articles 48-50 are supplemented with those of Law No 32/1968 on the Establishment and Punishment of Contraventions.

Chapter V
Final Provisions

Article 52. The present law goes into effect 60 days after the date of publication in BULETINUL OFICIAL AL REPUBLICII SOCIALISTE ROMANIA.* On the date that it goes into effect, any contrary provisions are repealed.

---

* With the exception of the provisions of articles 7-14 and of Article 33, Letter d, which are applied from the date of publication of State Council Decree No 184/1980.

CONSTRUCTION WORK IN FOREIGN COUNTRIES, 1974-1979

Belgrade EKONOMSKA POLITIKA in Serbo-Croatian 14 Jul 80 pp 21-24

[Text] According to date recently published by the Federal Bureau of Statistics, Yugoslavian building contractors completed capital investment projects with a value of about $1.2 billion outside the borders of the SFRY [Socialist Federal Republic of Yugoslavia] last year. This is an increase of 8.9 percent over the total for 1978. Construction projects were carried out in 48 countries, of which 15 were in Asia (with a value amounting to 34.1 percent of the total given above), 13 were in Africa (32.7 percent), 13 were in Europe (32.5 percent), and 3 were in South America. Work completed in the developing countries accounted for 67.4 percent of the total; in the industrialized countries, 17.4 percent, and in the socialistic countries of Eastern Europe, 15.2 percent. What is the story behind these data?

The fundamental reason that building contractors have taken on jobs in foreign countries is to employ their construction capacity more fully, especially since the demand for their services in the domestic market has not had a uniform rate of growth. Moreover, this type of employment offers possibilities for the creation of claims payable in foreign currency, or for the import of certain equipment and material. No less a motive is the better earnings, especially for skilled workers belonging to construction and related organizations. Finally, there is both a broader motive and interest for contractors to go abroad. This concerns the possibility of exporting other goods and services, of exchanging techniques and technology, and in general of creating a basis for a higher form of economic collaboration with foreign countries.

The present level of involvement of building contractors in foreign countries is rather modest if one is concerned with the realization of these efforts. The number of domestic workers employed in the construction of capital investment projects abroad is between 3 and 4 percent of the total number employed in Yugoslavian construction (Table 1). It would be difficult

to maintain that the level of employment in foreign countries is a crucial factor of stability, taking into consideration the level of employment in the construction industry as a whole. Nor does the fact that the worker employed on projects which are being constructed for foreign investors realizes 2.5 to 3 times greater total income than his colleague employed on domestic construction projects (or about 1.5 times if workers of the domocile country are also included in the number employed on foreign building sites) change the accuracy of this statement.

Key:

1. In thousands
2. Total number employed in construction in SFRY
3. Number of Yugoslav workers on construction sites abroad
4. Number of foreign workers on construction sites abroad
5. (Data from the Federal Bureau of Statistics)

The income in foreign currency from the performance of capital investment work in foreign countries amounts to about 40 percent of the total value of this work. Of course, we are speaking here of the average amount (in the last 5 years), which means that in a certain, albeit smaller, number of jobs, a significantly greater foreign currency income is realized (the most frequently cited example in this regard is the Belgrade Autoput construction firm, which realized a foreign currency income of 75 percent of the value of the completed work in jobs for the government of Gabon in 1976 and 1977). The share of the income from foreign currency from capital investment work abroad which is realized on the basis of the export of domestic equipment and materials is far less than the share which is obtained from nongoods foreign currency income (in which again the most important item is the export of the work force). The value of domestic equipment and materials used in projects which our contractors have built for foreign customers in the last several years has amounted to between 5 and 7 percent of the total value of the work. Moreover, the value of the equipment itself made up between 4 and 5 percent of the value of the investment.

It is estimated that the cost of materials and equipment ranges from between 60 to 80 percent in the total expenses involved in the construction of capital investment projects. More precise data cannot be given because this amount varies greatly depending on the type of project. As a rule,

it is higher with projects involved with hydraulic engineering (especially hydroelectric projects), somewhat lower with low-rise construction projects, and the lowest with high-rise construction, where the significant items are skilled workers (in building trades), with a relatively high level of manual labor.

It is apparent from the data provided by the Federal Bureau of Statistics (Table 2) that more than half of the working capacity of Yugoslavian contractors employed in foreign countries is involved in high-rise projects (the only exception is 1975). The level of high-rise construction is proportionally the highest in the industrialized countries and the lowest in the developing countries. The more valuable, or the more complex job, which besides the export of construction services also means the export of materials and equipment, is, therefore, "easier" to obtain in the less-developed countries, which, along with the fact that developing countries are, of course, unable to construct capital investment projects with their own operations and are directed to the import market, is the main reason that our contractors turn to this market.

8. Of the total: High-rise
9. Low-rise
10. Hydraulic engineering projects
11. Planning
12. According to regions: Developing countries
13. Socialist countries of Eastern Europe
14. Industrialized countries
15. (Data from the Federal Bureau of Statistics)

Measured by the value of work carried out, over two-thirds of the capacity of Yugoslvian contractors employed in foreign countries is engaged in the developing countries (Table 2). Moreover, the level of this engagement is increasing the most uniformly (the exception was in the year 1977, when the final account of unpaid claims from earlier years was carried out). There has been a modest growth in activity in the socialist countries of Eastern Europe for the last 6 years (with the exception of 1979), while in the industrialized countries it has fluctuated.

Lack of Involvement in Planning

One can conclude from these data that our construction organizations have mainly been the physical performers of foreign projects and technological determinations which also anticipate the use of foreign equipment and materials, or that as contractors they have been large buyers of the equipment and materials as well (the jobs for which this cannot be said are the exception, such as the capital investment work in Iraq where more of Yugoslavian plans and technological determinations are being used).

One reaches the same conclusion by also examining the participation of planning in capital investment work which has been completely finished in foreign countries (Table 2). The small part of the planners, on both an absolute and a relative level, in the capital investment work which has been completely finished (about 1.5 percent) is the result of the fact that on the whole they are hired independently, and this involvement is only in the extension of planning services or in the development of planning documentation for the performers of the work who have accepted the job on the basis of foreign offers. Only exceptionally are projects carried out which mean the realization and transfer of knowledge, techniques, and technology (something in this regard has been done only in the field of agroindustry). The basic reason for this is the fact that the planning organizations are not connected financially and technologically with economic areas which are interested in disposing of their products on the foreign market. Without this connection they are not, nor can they be, an exponent of producers, but appearing individually "from time to time" and at the same time maintaining buyer-seller relations, they cannot contribute in a more significant way to the disposal of goods through export by means of the performance of capital investment work in foreign countries. An "association" of planners and contractors would probably be the most acceptable solution to the problems connected to the financing of studies and the preplanning for investment undertakings for some of the developing countries (especially those whose needs are in accord with the strategy of our development).

Since studies, preplanning, and planning as a rule are the precursors to the export of materials, equipment, and technology of the countries who make these plans, it is the practice of the industrialized countries, who are far more successful than we are in the international market of capital investment work, to perform these jobs free of charge or with minimal

compensation, or if the planning is to be paid for, then it is most often financed. This type of investment, of course, is returned many times over if the job is obtained.

Reasons for Lack of Coordination

This type of practice, which is quite worthwhile in other countries, is almost inapplicable in our country under the present circumstances. Planners are not able to enter into the development of studies and pre-planning, and therefore not into the development of consulting and engineering work either (through which this type of job is actually carried out), first of all because the resources which are necessary for this are far greater than those which they possess, and in addition because of the fact that no one guarantees them that the product of this work will be accepted or paid for. No less of a problem in this regard is the fact that the development of consulting and engineering work also means a full insight into the production possibilities (and plans) of the domestic contractors and the producers of the equipment.

On the other hand, the contractors, if they pursue their own interests exclusively, are not willing to work according to domestic plans which mean the use of domestic equipment, construction machinery, and materials (or to finance their production), simply because of the fact that foreign producers provide prompter delivery of higher quality products at a lower price (along with servicing, more favorable credit conditions, and other benefits) than do domestic. The producers of equipment, again, are not prepared to share the risk of a joint excursion into the foreign market of capital investment work. It has been shown in former practice that in most cases they are not competitive enough with foreign firms, and that quite often they do not respond to the call of the contractors to offer their equipment (or materials), or that when they do offer it they give very short options causing a change in the agreed upon conditions depending on the conditions in the domestic market.

It is certainly not possible to increase the total impact of our appearance on the international market of capital investment work, or to overcome the problems with which this appearance is burdened, by measures which apply only to individual activities which participate in any sort of way in the export of goods and services through construction work. Taking on complex capital investment work in international bidding is objectively more and more dependent upon the existence of a strong and effective system in which those who perform the work and those who produce the cpaital investment and other equipment, the construction machinery, etc., are connected. Of course, the proper motive for the connection in such a system can only be the possibility that those who make up the system will realize a profit by these means. Therefore one can say that the former results of the export of construction work (as well as the other products exported by means of this) are first of all the expression of the immediate possibilities no only of the construction industry, but also of the whole economy. Because

as long as the industry which accompanies construction in foreign countries realizes a greater profit placing their products on the domestic market than they would by exporting these products (that is, while there is no justification according to income for export), there will not be any more essential changes with respect to the latest results of our participation in the international market of capital investment work. Moreover, without the creation of more favorable conditions for the economy as a whole, one should expect a narrowing of the extent of the investment of the construction services themselves as well. Considering that contractors have had up to now (and still have) an interest (more or less independently) in being employed in foreign countries because they realize a profit, which, according to some data, is about 10 percent of the total value of the project they are working on, because they employ their working capacity, because they improve themselves in a personnel, technical and technological, and organizational sense, as well as in other ways, this might be a motivation for the contractors themselves to become involved with tying themselves in with the other participants in the construction of capital investment projects.

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

CEMA ATTITUDE ON EEC PARTICIPATION VIEWED

Budapest MAGYAR HIRLAP in Hungarian 25 Jul 80 p 7

[Report by Sandor Nedeczky: "What Is the Topic of the Talks Between the CEMA and the EEC? A Clear Picture of the Situation"]

[Text] The two European organizations have been meeting for some time. The press and the official circles of the CEMA countries have limited their discussion up until now to the significance of the talks, and urged resolving differences of opinion in the name of mutual amenableness. Precisely in order to guarantee the undisturbed continuation of the present talks, certain circles refrained from criticizing certain stands of the EEC. Not so the press of the EEC. There, on the basis of detailed information--which was leaked on some details of the talks that are otherwise considered confidential--a conscious propaganda activity is taking place to influence public opinion. It is no accident that this so happens, for the EEC's delegation repeatedly refers to this manipulated, misinformed and preconceived public opinion in order to force its conceptions and will on the delegations of the CEMA and its member states.

The organs of the press and propaganda and certain representatives of the European Parliament are not sparing of destructive and provocative statements either. In these cases, the official representatives of the EEC refer to freedom of the press, freedom of speech and the immunity of parliament representatives, and say that these are only the opinions of the press or individual persons and politicians. They, that is, the EEC, have no sinister intentions at all and it is not their objective to undermine the unity of the CEMA and the socialist countries.

Still, there are two things apparent to the unbiased observer. One of them is that the EEC's official organs, the much advertised committee and its president and political executive responsible for foreign relations, and the Council of Ministers or its president have not found it necessary up to now to distance themselves publicly and officially from these irresponsible statements. The other striking phenomenon is that the delegation of the EEC represents views which seem to serve the above-mentioned political and provocative goals. This is possibly only accidental.

but perhaps not. For this reason it is important, then, to give a clear picture to the public. This is the objective of the few thoughts below.

Recognition, Lack of Recognition

This question was for a long time the focal point of the disagreement between the CEMA countries and the EEC. The Western propaganda that accompanies the present talks gives this an appearance that the CEMA countries, too, have finally accepted and recognized this reality which has been accepted and recognized by every other nation. The everyday use of language does not differentiate between acceptance and recognition. Interstate relations, however, take the form of rights and obligations, and there is a great difference between a country's acceptance of something--i.e., the recognition of a fact--and the recognition of something in an appropriate form--i.e., legal acceptance. The former is the given country's own sovereign will and act, with no obligation. The latter is an act agreed upon by contract, therefore it obliges. The EEC, they say, is a reality. This is true. This reality, however, has several aspects, especially if we view it from our own economic and political interests. The fact, for instance, that the EEC is a customs union, i.e., there are no duties between its own countries, and that it has external customs tariffs, is an absolute fact that "must be recognized." But such customs union affects the interests of other countries as well, for duties afflict the prices of these countries when they enter the EEC's customs area. Thus, in order to recognize customs unions by international law, it is not enough to state the fact that a customs union has been created, but it also must be stated whether and to what extent the given customs union has fulfilled the obligations that are set in international contracts. From this aspect, the EEC's customs union character has not been entirely and legally recognized. This is so not because of the CEMA countries' attitude but because of the reservations of the EEC's most important trade partners.

It must be noted at the same time that the EEC's customs union character was de facto recognized by all of its important trade partners.

Economy and Politics

The EEC is not only a customs union but also an economic union, and a joint noncustoms-policy was established in certain sectors such as agriculture (for in the area of agriculture, there are still customs-like levies between individual EEC countries). The United States, for example, did not recognize this joint agricultural policy for a long time. Legal recognition came about only in 1979 during the GATT conference, and it had its price, of course. All of this illustrates that there is a significant difference between recognition and acceptance; this difference is not only formal but affects economic interests.

In addition, the EEC is not only an economic but also a political union. This was never denied by the EEC itself; on the contrary, it openly

proclaims it even today. The only time it keeps bashfully quiet about it is when it directs its propaganda toward the socialist countries. It is only us they want to make believe that they are only an economic organization or integration. Their argument for a long time was that you and I are both integrations, you cannot blame us for anything.

If we take a glance at the so-called Pact of Rome which created the EEC, we will see that all of its pores smell of politics. It commits its member states not only to implement the so-called free economy (this elicited the criticism of the socialist and communist parties of certain EEC countries; these parties are talking about the Europe of the monopolies) but also to engage in foreign policy. One of the signs of this is that the Pact of Rome that created the EEC reflects a situation which corresponds to the situation before the agreements between the two Germanys. With reference to West Berlin, it contains orders which cannot be guaranteed to be in harmony with the relevant four-power agreements.

Thus, he who confers with the EEC must also consider the political reality. But this is not tantamount with the legal acceptance of these and with giving up our own interests. This is why we must talk about it and this is why the conferences are taking place.

In addition to this, the EEC also created a joint trade policy. The essence of this that is relevant to us is that it is the EEC that acts and makes contracts in the name of and instead of the member states. But the Pact of Rome also states that this does not affect the earlier contracts of the individual countries either from the aspect of rights or from that of obligations. This is the way it happened, with the exception of certain socialist countries. Some EEC countries canceled the earlier contracts with them which contain, among other things, most-favored-nation treatment—which means the minimum of normal relations. This is how they wanted to force the socialist countries to "recognize" the EEC unconditionally and regardless of their interests. It must be noted that this did not happen in our case. Obviously because, as a signatory, we made contracts with all EEC countries and with the EEC itself for most-favored-nation status, which is unconditional and cannot be canceled.

Separate Contracts?

After this came a much-advertised proposal that every single socialist country should sign a separate contract with the EEC. This contract scheme (schema d'accord) was greatly supported by propaganda. They made it to appear as if it were a constructive step; however, the propaganda, the press and certain politicians talked about other things as well. They argued that this contract was beneficial for the smaller socialist countries because they would be thus freed from CEMA's straitjacket and might receive special benefits. This objective was never refuted by the official organs of the EEC and the governments of the member states. The behavior of the CEMA countries in this matter was cautious. The EEC's

propaganda viewed this with a wonder full of resentment. Here you are, an outstanding opportunity, an advantageous proposal, and they do not even reply. We can only wonder at this wonder. Or some people thought that we were not aware of their intentions, or thought that we could not wait to fall into the embracing arms of the EEC, an organization which in the meantime loudly proclaims that it does not want to regulate its relations with the socialist countries on the basis of the most-favored-nation treatment and lack of discrimination.

CEMA and its member states in turn made a proposal in 1975 that the two organizations should begin talks with consideration of their own areas of competence. The talks are being conducted on this basis.

YUGOSLAV-HUNGARIAN COMMODITY TRADE LISTS FOR 1979

Belgrade MEDJUNARODNI UGOVORI (supplement to SLUZBENI LIST SFRJ) in Serbo-Croatian No 8, 17 Jul 80 pp 310-314

[Commodity lists from trade protocol ratified 6 April 1979 in Belgrade by the Federal Executive Council and signed by FEC chairman Veselin Djuranovic]

[Text] List A/1979. Exports From the People's Republic of Hungary to the Socialist Federal Republic of Yugoslavia, in thousands of dollars U.S.

No 1	Designation 2	Unit of Measurement 3	Quantity 4	Value 5
1	Machines, equipment, road and rail vehicles, instruments, products of the electronic industry, volume products of machinebuilding, and components	Dollars		71,000
	Breakdown:			
	Cooperation in the production of highway vehicles and in the motor industry	"		30,000
	Other cooperation in industrial production	"		5,000
	Electric motor trains	"		10,000
	Mechanical equipment for locomotives and parts for rail vehicles	"		1,000
	Port equipment (cranes and parts)	"		1,000
	Machinery and equipment for the Danube-Tisa-Danube Canal	"		6,000
	Machine tools	"		2,000

List A/1979 (continued)

1	2	3	4	5
	Agricultural machines and equipment for the food processing industry	Dollars		2,000
	Equipment for the electrical products industry, lamp parts and other components	"		5,000
	Parts for highway vehicles and garage equipment	"		4,000
	Miscellaneous instruments and components	"		1,000
	Tools and products of the metal manufacturing industry	"		4,000
2	Long-term cooperation			
	Pulpwood for Djuro Salaj of Krsko	Cubic meters (stacked)	280,000	
	Pulpwood for Matroz of Sremska Mitrovica	"	97,000	
	Ammonia for the Bor Mine and Smeltery, Generaleksport of Belgrade	Tons	27,500	
	Ammonium sulfate for the Bor Mine and Smeltery, Generaleksport of Belgrade	"	17,000	
	Carbamide for the Bor Mine and Smeltery, Generaleksport of Belgrade	"	17,000	
	PVC pellets for the Bor Mine and Smeltery, Generaleksport of Belgrade	"	4,200	
3	Products of ferrous metallurgy	"	66,000	
4	Exchange of products of ferrous metallurgy	Dollars		20,000
5	Products of electrometallurgy	"		2,700
6	Ethylene	Tons	10,000	
7	Propylene	"	10,000	
8	Polypropylene	"	6,000	
9	Sulfuric acid	"	60,000	
10	Synthetic resins	"	1,700	
11	Sodium hydroxide	"	20,000	
12	Butyl and isobutyl acetate	"	1,200	
13	Creosote for impregnating wood	"	4,000	
14	Ammonia	"	50,000	
15	Chemicals for plant protection	Dollars		500

List A/1979 (continued)

1	2	3	4	5
16	Carbamide	Tons	20,000	
17	Motor vehicle tires and industrial rubber	Dollars		2,000
18	Miscellaneous chemical products	"		3,000
19	Drugs, raw materials for the pharmaceutical industry and laboratory raw materials	"		2,500
20	Propane-butane	Tons	40,000	
21	Gasoline, reformed	"	10,000	
22	Blown oils	"	6,000	
23	Paraffin	"	2,000	
24	Finishing in the petroleum industry	Dollars		1,800
25	Silica sand	Tons	45,000	
26	Molding sand	"	8,000	
27	Perlite	"	15,000	
28	Cement	"	160,000	
29	Pulpwood	Cubic meters (stacked)	50,000	
30	Miscellaneous products of the lumber and paper industries	Dollars		2,000
31	Consumer goods	"		13,000
	Breakdown:			
	Textile products	"		6,500
	Housewares, camping furniture and camping supplies	"		4,000
32	Books, films and other products of printing and publishing	"		1,000
33	Raw and processed foods (including vegetable oils)	"		10,000
34	Border trade	"		9,500
35	Services (carriage, tourism, etc.)	"		54,000

List B/1979. Exports From the Socialist Federal Republic of Yugoslavia to the People's Republic of Hungary, in thousands of dollars U.S.

No 1	Designation 2	Unit of Measurement 3	Quantity 4	Value 5
1	Machines, equipment, road and rail vehicles, instruments, products of the electronic industry, volume products of machinebuilding, and components	Dollars		65,000

List B/1979 (continued)

1	2	3	4	5
	Breakdown:			
	Cooperation in the production of highway vehicles and in the motor industry	Dollars		30,000
	Other cooperation in industrial production	"		5,000
	Power engineering equipment, equipment and parts manufactured by the electrical products and electronics industries (including storage batteries)	"		5,000
	Construction and mining machines and parts	"		500
	Pumps	"		2,600
	Machine tools	"		1,000
	Agricultural machines and equipment for the food processing industry	"		1,800
	Parts for ships and cranes	"		1,000
	Parts for highway vehicles and garage equipment	"		4,000
	Parts for railroad cars	"		1,300
	Industrial fittings and couplings	"		5,800
	Tools and products of the metal manufacturing industry	"		7,000
2	Long-term cooperation			
	Cellulose for Lignimpex of Budapest (Djuro Salaj of Krsko)	Tons	40,000	
	Cellulose for Lignimpex of Budapest (Matroz of Sremska Mitrovica)	"	13,000	
	Monobasic ammonium phosphate for Chemolimpex of Budapest (Bor Mine and Smeltery)	"	70,000	
	Triple superphosphate for Chemolimpex of Budapest (Bor Mine and Smeltery)	"	100,000	
3	Ferroalloys (ferrochromium, ferromanganese and ferrosilicon)	"	5,000	
4	Castings	Dollars		1,000
5	Products of ferrous metallurgy	"		2,500
6	Exchange of products of ferrous metallurgy	"		20,000

List B/1979 (continued)

1	2	3	4	5
7	Coke	Tons	50,000	
8	Copper and semifinished copper products	Dollars		4,500
9	Lead	Tons	2,400	
10	Zinc metal	"	5,000	
11	Metallic silicon	"	600	
12	Cable	Dollars		500
13	Raw materials for polyurethanes, including polyols	Tons	2,000	
14	Nitrogen-phosphorus-potassium fertilizers	"	50,000	
15	Monobasic calcium sulfate	"	5,000	
16	Tribasic sodium phosphate	"	2,000	
17	Zinc oxide	"	1,000	
18	Methanol	"	8,000	
19	Boric acid	"	1,000	
20	Titanium dioxide	"	400	
21	Chemicals for plant protection	Dollars		1,500
22	Low-density polyethylene	Tons	5,000	
23	Motor vehicle tires and industrial rubber	Dollars		2,000
24	Miscellaneous chemical products	"		2,000
25	Drugs, pharmaceutical and laboratory raw materials	"		1,000
26	Barite	Tons	12,000	
27	Alumina	"	7,000	
28	Miscellaneous products of the nonmetallic minerals industry, including refractory material	Dollars		1,500
29	Slaked lime	Tons	30,000	
30	Beech lumber	Cubic meters	10,000	
31	Railroad ties	"	10,000	
32	Miscellaneous products of the paper industry	Dollars		1,300
33	Cigarette paper	Tons	600	
34	Rayon cord	"	500	
35	Polyester fiber	Dollars		2,000
36	Textile finishing	"		1,500
37	Consumer goods	Dollars		13,000
	Breakdown:			
	Textile products	"		6,500
	Housewares	"		4,000
38	Books, films and other products of the printing and publishing industry	"		1,000

Li-t B/1979 (continued)

1	2	3	4	5
39	Raw and processed foods, including deliveries on the basis of the Danube-Tisa-Danube Canal and tobacco	Dollars		9,500
40	Border trade	"		9,500
41	Services (carriage, tourism, etc.)	"		83,000

List C/1979. Exports From the People's Republic of Hungary to the Socialist Federal Republic of Yugoslavia Under the Exchange of Goods, Services and Economic Cooperation in Border Trade, value in thousands of dollars U.S.

No	Designation	Value
1	2	3
	Industrial consumer goods	3,100
1	Metal housewares and small farm machinery	800
2	Housewares made of synthetics, chemical products and cosmetics	200
3	Glass products, including glass bottles	400
4	Light bulbs	100
5	Textiles	800
6	Housewares	100
7	Exchange between department stores	700
	Agricultural products and foodstuffs	2,750
8	Eggs for hatching	300
9	Poultry for the food processing industry	1,000
10	Leguminous vegetables (peas, buckwheat, sorghum seed, etc.)	400
11	Alcoholic beverages in bottles	50
12	Miscellaneous agricultural products and foodstuffs	1,000
	Building and other materials	1,650
13	Building materials for flood control	1,450
14	Limestone for the sugar industry	200
	Production cooperation (finishing and services)	400
	Fair exhibits	100
	Exchange of consumer goods under the general contract between Konsumex and the Pomurke Agroindustrial Combine	1,500

List D/1979. Exports From the Socialist Federal Republic of Yugoslavia to the People's Republic of Hungary Under the Exchange of Goods, Services and Economic Cooperation in Border Trade, value in thousands of dollars U.S.

No	Designation	Value
1	2	3
	Industrial consumer goods	4,300
1	Metal housewares and industrial goods (electrical products, tools, bicycles, etc.)	800
2	Chemical products and cosmetics	900
3	Footwear	200
4	Soles and patterns	100
5	Sporting goods and toys	100
6	Textiles	800
7	Housewares	500
8	Motor vehicle tires	200
9	Exchange between department stores	700
	Agricultural products and foodstuffs	3,100
10	Canned foods	200
11	Chestnuts	200
12	Beer	2,500
13	Cigarettes	150
14	Liquor	50
	Building and other materials	100
15	Hydrated lime and tiles	100
	Production cooperation (finishing and services)	400
	Fair exhibits	100
	Exchange of consumer goods under the general contract between the Pomurke Agroindustrial Combine and Konsumex	1,500

YUGOSLAV-CZECHOSLOVAK COMMODITY TRADE LISTS FOR 1979

Belgrade MEDJUNARODNI UGOVORI (supplement to SLUZBENI LIST SFRJ) in Serbo-Croatian No 8, 17 Jul 80 pp 315-317

[Commodity lists from trade protocol ratified 31 May 1979 in Belgrade by the Federal Executive Council and signed by FEC chairman Veselin Djuranovic]

[Text] List A/1979. Exports of Commodities From the Socialist Federal Republic of Yugoslavia to the Czechoslovak Socialist Republic

No 1	Designation 2	Unit of Measurement 3	Quantity 4	Value, 000 $ 5
1	Raw and processed foods, including fresh fruit, vegetables, prunes and seed			5,000
2	Canned fish			3,500
3	Tobacco and tobacco manufactures			10,000
4	Wine			1,000
5	Sorghum straw			1,500
6	Veneer and panelboard	Cubic meters	10,000	
7	Lumber	"	1,500	
8	Miscellaneous paper, cardboard and paper containers			1,000
9	Bauxite	Tons	150,000	
10	Chromium ore concentrate	"	10,000	
11	Electrolytic zinc	"	5,500	
12	Zinc dust	"	6,000	
13	Castings of zinc alloys	"	300	
14	Rolled and drawn aluminum products, including aluminum tube	"	2,000	
15	Rolled and drawn copper and brass products	"	500	
16	Nonferrous metal fittings			2,000

List A/1979 (continued)

1	2	3	4	5
17	Miscellaneous chemical raw materials and products, including dibasic calcium phosphate and exchange of chemical products			17,000
18	Miscellaneous pharmaceutical raw materials, products and drugs, including veterinary preparations			5,500
19	Deliveries under a specific contract			6,300
20	Products of the electrical equipment industry, including telephone cable			9,500
21	Passenger cars	Units	2,000	
22	Machines, including machine tools, equipment and parts and agricultural machines			45,000
23	Railroad cars, tanks and parts for railroad cars			5,000
24	Parts and accessories for motor vehicles			7,500
25	Gears			12,000
26	Tools and instruments			4,000
27	Miscellaneous metal products, including plumbing fittings, antifriction bearings, typewriters, etc.			3,000
28	Castings and forgings			7,200
29	Storage batteries			3,000
30	Motor vehicle tires and industrial rubber			5,300
31	Exchange of products of ferrous metallurgy			15,000
32	Textiles and textile products			16,000
33	Hemp and tow			1,200
34	Footwear and leather products			5,000
35	Consumer goods, including housewares			14,000
36	Viscose fiber, polyols and polyurethane products	Tons	3,000	
37	Electrocorundum			2,000
38	Books, films and printing and publishing services			500
39	Exchange of building materials, including asbestos-cement products			5,000

List A/1979 (continued)

1	2	3	4	5
40	Construction of building projects and construction services			35,000
41	Transportation services, including petroleum pipeline			50,000
42	Tourism			18,000
43	Miscellaneous invisibles			9,000
44	Deliveries related to industrial cooperation			50,000
45	Deliveries related to the Danube-Tisa-Danube contract			5,400
46	Deliveries under the NK [expansion unknown] contract			10,000
47	Deliveries related to the Jadran Department Store			1,000
48	Cooperation in agriculture: UPI of Sarajevo, AGROKOMERC of Velika Kladusa, and others, with TRANSAKT of Prague			2,000
49	Electric power			6,000
50	Deliveries under the contract between KTK [expansion unknown] of Visoko and METALIMEX of Prague			10,700
51	Miscellaneous			2,000

List B/1979. Exports of Commodities From the Czechoslovak Socialist Republic to the Socialist Federal Republic of Yugoslavia

No	Designation	Unit of Measurement	Quantity	Value, 000 $
1	2	3	4	5
1	Coking coal	Tons	600,000	
2	Rolled and drawn products of ferrous metallurgy, including semifinished products	"	110,000	
3	Miscellaneous products of ferrous metallurgy			5,000
4	Machines and equipment, including machine tools, 3,000 tractors, electrical equipment and other capital goods			95,000
5	Miscellaneous products of the electrical products industry			1,500
6	Miscellaneous metal products			2,000
7	Trucks and special vehicles			14,000

List B/1979 (continued)

1	2	3	4	5
8	Passenger vehicles	Units	7,500	
9	Parts for highway vehicles and tractors			8,000
10	Parts for railroad cars			1,000
11	Antifriction bearings			3,000
12	Tools and instruments			4,000
13	Deliveries under the special contract			8,200
14	Miscellaneous pharmaceutical raw materials and products			1,500
15	Miscellaneous chemical raw materials and products, including monoethylene glycol and exchange of chemical products			19,000
16	High-density polyethylene	Tons	5,000	
17	Polypropylene	"	5,000	
18	Synthetic rubber	"	1,500	
19	Tires and industrial rubber, including tires for construction machines			8,000
20	Raw and fired clay	Tons	24,000	
21	Kaolin	"	35,000	
22	Cement	"	50,000	
23	Exchange of building materials, including asbestos-cement products			5,500
24	Glass products			3,500
25	Glass wool			1,700
26	Exchange of products of ferrous metallurgy			15,000
27	Textiles, footwear and intermediate products			22,500
28	Consumer goods, including musical instruments and sporting goods			16,000
29	Wood products			5,400
30	Pulpwood			6,000
31	Miscellaneous paper, including kraft paper and scrap paper			3,000
32	Books, films and printing services			500
33	Deliveries under industrial cooperation			50,000
34	Deliveries under the Danube-Tisa-Danube contract			500
35	Deliveries under the NK [expansion unknown] contract			14,000

List B/1979 (continued)

1	2	3	4	5
36	Deliveries under the aluminum contract			16,000
37	Cooperation in agriculture between UPI of Sarajevo, AGROKOMERC of Velika Kladusa, and others, on the one hand, and TRANSAKT of Prague on the other			15,000
38	Tourism			3,000
39	Transportation services, including gas pipeline			20,000
40	Deliveries under the contract between KTK [expansion unknown] of Visoko and METALIMEX of Prague			10,700
41	Miscellaneous			8,000

YUGOSLAV-BULGARIAN COMMODITY TRADE LISTS FOR 1979

Belgrade MEDJUNARODNI UGOVORI (supplement to SLUZBENI LIST SFRJ) in Serbo-Croatian No 8, 17 Jul 80 pp 318-321

[Commodity lists from trade protocol ratified 31 May 1979 in Belgrade by the Federal Executive Council and signed by FEC chairman Veselin Djuranovic]

[Text] List A/1979. Exports From the People's Republic of Bulgaria to the Socialist Federal Republic of Yugoslavia

No 1	Commodity Designation 2	Unit of Measurement 3	Quantity or Value 4
1	Forklift trucks (electric and internal combustion)	000 $	2,500
2	Electric hoists	"	400
3	Spare parts for forklift trucks	"	500
4	Greenhouses	"	6,000
5	Irrigation and drainage systems	"	4,000
6	Metal fabrications	"	6,000
7	Diesel engines	"	100
8	Battery separators and elements	"	1,000
9	Rakes	"	100
10	Agricultural machines and spare parts	"	1,000
11	Miscellaneous machines, equipment and mutual deliveries under cooperative arrangements	"	4,000
12	Cooperation in the production of washing machines	"	500
13	Products of the electronics and electrical equipment industries	"	2,000
14	Complete equipment for warehouses	"	1,000
15	Metal- and woodworking machines	"	500
16	Bearings	"	150

List A/1979 (continued)

1	2	3	4
17	Fifth wheels and parking wheels for trailers	000 $	500
18	Cables and conductors	"	200
19	Exchange of products of ferrous metallurgy	"	8,000
20	Processing of aluminum	"	4,000
21	Processing of nonferrous metals and semi-finished products	"	1,000
22	Products of nonferrous metallurgy	"	700
23	Metal products (special shapes for electric and gasoline forklift trucks)	"	2,000
24	Hot rolled strip	"	80
25	Tinplate	Tons	3,000
26	Lead	"	5,000
27	Zinc in ingots	"	2,000
28	Scrap iron	000 tons	30
29	Sodium nitrate	Tons	2,000
30	Sodium nitrite	"	500
31	Carbon disulfide	"	2,000
32	Tribasic sodium phosphate	"	3,000
33	Ammonia	000 tons	5
34	Ammonium sulfate	"	15
35	Carbamide	"	20
36	Borax	Tons	200
37	Paraffin	"	2,000
38	Acetone	"	2,000
39	Ethylene oxide	"	1,000
40	Acrylonitrile moncmer	000 tons	10
41	Styrene monomer	Tons	200
42	Red lead oxide	"	600
43	Litharge	"	300
44	Diethylene glycol	"	300
45	Phenol	"	2,000
46	Propylene	"	1,000
47	Toluene	"	3,000
48	Arizol	"	3,000
49	Liquid chlorine	"	2,000
50	Chemicals for plant protection	000 $	100
51	Products of the petroleum industry	"	1,000
52	Propane-butane gas	000 tons	20
53	Tires and rubber products	000 $	100
54	Miscellaneous chemical products	"	3,000
55	Kraft and other paper pulp	"	800
56	Miscellaneous paper and cardboard	"	1,000
57	Wood chipboard	"	2,000
58	Charcoal	Tons	1,000
59	Cement	000 tons	50

List A/1979 (continued)

1	2	3	4
60	Raw and processed foods	000 $	3,000
61	Seed and nursery stock	"	500
62	Pharmaceutical raw materials and cosmetic products	"	3,000
63	Essential oils and plants	"	400
64	Textiles, textile raw materials, garments, textile accessories and trimming	"	4,000
65	Raw hides and leather products	"	3,000
66	Synthetic fibers and yarn	"	500
67	Consumer goods	"	3,000
68	Border trade	"	5,000
69	Carriage	"	4,000

YUGOSLAV-POLISH COMMODITY TRADE LISTS FOR 1979

Belgrade MEDJUNARODNI UGOVORI (supplement to SLUZBENI LIST SFRJ) in Serbo-Croatian No 8, 17 Jul 80 pp 322-326

[Commodity lists from trade protocol ratified 31 May 1979 in Belgrade by the Federal Executive Council and signed by FEC chairman Veselin Djuranovic]

[Text] List A/1979. Exports From the Socialist Federal Republic of Yugoslavia to the People's Republic of Poland in 1979

No	Item Designation	Unit of Measurement	Quantity	Value, 000 $
1	2	3	4	5
1	Deliveries based on cooperation and specialization			85,900
	Breakdown:			
	Motor vehicle industry			40,500
	Ignition devices in the motor industry			500
	Automotive electrical equipment			1,000
	Industry of tractors and farm machines			25,000
	Including spare parts alone	$2 million		
	Rail vehicle industry			300
	Electronics industry			6,000
	Electrical equipment industry			2,000
	Machine tool industry			6,400
	Including woodworking machines	$400,000		
	Construction and roadbuilding machine industry			2,000
	Industry of household appliances and municipal service equipment			1,300
	Household plumbing fittings			300

List A/1979 (continued)

1	2	3	4	5

ENERGY PROBLEMS, CONSUMPTION EVALUATED

Structural Changes in Primary Energy Sources

Prague PLANOVANE HOSPODARSTVI in Czech No 7, 1980 pp 1-6

[Article by Vitezslav Vinklarek, deputy chairman of the State Planning Commission]

[Text] The development of the Czechoslovak economy in the postwar period made possible truly revolutionary changes in the life of our society. From the time when the problem was to make sure that people had enough to eat and adequate clothing and shoes, a situation has emerged in which the vast majority of the population, rather than only a few privileged individuals, is selectively choosing from among better types of food, clothing and footwear. Today even young families consider a high living standard and the best of everything for children, as quite normal. Whole cottage communities have sprouted in the countryside, we are establishing second residences for our leisure time, and we travel abroad in large numbers during summer vacations. We have developed and maintained a high European living standard which, unlike those in the capitalist countries, has its socialist certainties.

The global situation, however, has also undergone changes. The most significant of these with respect to the CSSR economy are the changes on the world markets of fuels, energy, raw materials and foodstuffs. Their procurement is much more difficult, both physically and in economic terms. In the Czechoslovak economy, with its own insufficient and limited raw material base, this causes severe problems. The main consequence of the 1973-74 changes, and their escalation in 1978-79 and thereafter, lies in the fact that the demands of fuels, raw and other materials on the national income are growing. In the long run this acts the same as if the national income's very formation were slowing down.

The changes at home and throughout the world levy new demands on our economy and the resources developed within it. It goes without saying that the nature of these demands is not so much quantitative as primarily qualitative. In production, and gradually also in consumption management, we

must find a way to focus attention on problems of quality. We need to reach a point where, through better quality and more intensive use of labor, fuels, energy, raw and other materials in production, we turn out products of ever-rising technological and qualitative level, and where these products become more profitable especially in foreign markets, but also in domestic markets.

Among the areas which most influence the effectiveness of the formation and allocation of national revenue in the present period of development is the fuels and energy complex. Physical facts might create the impression that everything is in good order, that here we have a process which reflects the growth of efficiency, and that the only thing to be concerned about is its pace, i.e., possible acceleration.

For each billion korunas of national revenue we use up the following quantities of primary energy sources (in thousands of tmp [tons of standard fuel]):

	1970	1975	1980 (est)
	259	225	210
drop	--	34	15

The lowering of energy demands on national revenue formation is thus clear. What is also visible, however, is its slowdown. This is obviously linked to higher use of solid fuels which occurred following the sharp rise in the price of oil in 1973-74 (and transformation of energy and its refining is less effective when based on solid fuels). There is no doubt that this process is also influenced by a slower growth in the national income which occurred in recent years.

The question of lower pace in energy demand assumes a different dimension when we examine how much it costs to procure a given quantity of primary energy sources. Without great analysis and evidence, I can state that 210,000 tmp in 1980 is considerably more expensive than 225,000 in 1975, and 259,000 in 1970. Stated simply, the cost of primary sources needed to form a unit of national income, is growing. In other words, it is a fact that either the pace of lowering energy demand slowed down too much, or the energy structure has become too costly. It seems that both aspects have become the order of the day.

Let us first examine what types of fuels (judged by the cost of their production) are increasing their significance in the overall structure of primary energy sources for domestic use. In this, let us consider that

--while domestic sources are acquired under steadily worsening conditions, their cost nevertheless rises relatively slowly (this, of course, does not mean that we are indifferent to this rise and that funds for this purpose can be approved lightly),

--imported sources consist largely of oil and natural gas. Their cost has risen enormously in two waves, first in 1973-74, and second in 1978-79, and continues to rise.

Supplying the growing domestic consumption needs, under above-mentioned circumstances, is developing as follows (in millions of tmp):

	1970	%	1975	%	1980(est)	%
Domestic sources	58.4	71.9	58.7	63.0	61.5	57.9
Sources from import	22.8	28.1	34.5	37.0	44.7	42.1
Domestic use overall	81.2	100.0	93.2	100.0	106.2	100.0

Constantly rising in the past decade is the percentage of imports to meet domestic consumption needs of primary energy. Even without documentation, I must say that this picture, i.e., growth of imported fuels, is also clearly visible in securing the production of electricity and heat. The cost growth per unit of primary sources needed per unit of national revenue results, in the first place, from the percentage growth of expensive imported fuels, especially oil, in the overall domestic consumption of primary energy sources.

Thus arose a whole new situation. Ten or 15 years ago, we promoted the line in the national economy of using oil and its byproducts to the maximum extent possible for the needs of the energy industry, switching from electrification of long-distance and urban transport to diesel power, and utilization of primarily motor and heating oil as a factor in labor productivity growth in mining and the other industries, as well as in construction and agriculture. For example, for long years we were satisfied with virtual stagnation in the extraction of energized brown coal--for all practical purposes, until 1975. All that was correct then, in a period of cheap (and getting cheaper) oil and low-cost raw materials. However, to continue this policy even now, especially with the argumentation "why, for 10 years you were pushing us into it," would be an anachronism, to say the least. Failure to understand that to operate, in a period of expensive oil and raw materials, the same way we did when they were inexpensive, would represent a heavy loss to the national economy.

Naturally, the new situation does not mean immediate abolition of all past practices and introduction of new ones. The national economy does not tolerate abrupt measures which have "catastrophic" consequences. Moreover, we have been reacting to the new conditions to some extent ever since 1974. We slowed down the growth of oil-related product consumption for energy purposes, and even in motorization, etc. The new situation, however, requires more consistency and continuation in the adopted course in a more programmatic and thoughtful manner in all respects. The price rise which we are currently experiencing again on all world markets, is beginning to affect our economy to the full extent--the grace period we were granted, and still are, by virtue of the system of price formation with respect to

the Soviet Union and the other socialist countries, is beginning to be exhausted. What, then, is the situation; what are the conditions and remedies; and what may, or must, be the approach to resolution? If in the immediate future we can still count on a modest rise in oil processing, in a more long-term view it will be wise to expect a certain decrease. Simultaneously, oil consumption for chemical purposes will apparently continue to grow. The same will be true in mechanization, even though such consumption is subject to all-embracing effectiveness and economy standards. The production capability of light particles in oil must be raised by the cracking process. This is one side of the problem which, however, is linked with the lower projection of the dark particles, thus with lower oil utilization for energy purposes. In our circumstances, this lower oil utilization cannot be replaced by anything but energized coal and nuclear electricity. That is the other side of our problem. Consequently, more intensive oil processing, more extraction of brown coal especially, and more nuclear electric power, constitute the Gordian knot, the cutting of which, as relates to this branch, will determine the future growth of effectiveness of our national economy, as a gradual resolution of a number of problems in the fuels and energy balance in our country.

This means that we are on the threshold of important changes in the structural makeup of the national economy. These changes must seek to ease the burden on national income formation placed on it by the situation in fuels and energy. As the following will demonstrate, this involves a whole series of changes.

What problems and tasks must we focus on? What needs to be done?

1. Remove gasoline as rapidly as possible from use in the energy industry. As surprising as it may seem, we are using 100,000 tons of it for these very purposes. Even today, it is the most expensive fuel and there is no doubt that when it is manufactured by the cracking process, it will be even more expensive. Most likely, the best substitute must be natural gas.

The use of gasoline as fuel must, for all intents and purposes, be limited to private motor transport and even there technological progress must assist in reducing standard consumption. Efficiency in the use of gasoline in this one area is achieveable. That particular use of gasoline aside, it must be considered a form of petrochemical raw material the relative value of which will be reassessed in future phases of the reproduction process. In this regard, we should note that the replacement of certain products made from domestic raw materials (glass, ceramics) by plastics, is currently not always desirable. On the contrary, by doing this there is considerable wasting of plastics.

2. More effective and economical handling of motor and heating oil throughout the national economy, since it is the second most expensive fuel. This is especially important in

--transportation, where (in addition to elementary discipline, such as full utilization of each trip) we face two basic problems: The range of transport operations as such, and the type of fuel power base. The range of transport operations is tied to the overall national economic tendencies, the pace of development, the extent of fuels, metals, and raw materials consumption, their relative values, etc. Intensification in national economic development therefore represents the principal criterion in determining the scope of transport operations, as well as in lowering oil consumption. In this connection we are about to strengthen the role of rail transport in the overall transportation structure, in both freight and passenger operations. The fuel power base which has in the past relied on higher use of diesel oil, will henceforth have to be reoriented toward electricity. Motor oil for long-distance, but also urban, transport, will have to be replaced by nuclear electricity. This constitutes a major structural change, the implementation of which will result in electrification of railroads, as well as urban mass transit, and in production restructuring of locomotives, buses, and streetcars. This must be synchronized in time with the construction of nuclear electric plants and the increase in electricity production therein;

--in the construction industry we must avoid projects which require great movement of materials and thus high consumption of motor oil. This is, of course, linked with the concepts of capital investment and its orientation in greater measure not on large construction projects with extensive ground operations, but rather on such structures as can be built with less movement of materials than was the case before. The use of motor oil in this area for heating will not be possible in the future.

--in agriculture today we can no longer manage without extensive mechanization and ensuing consumption of motor oil. We must, however, avoid its use for other than these technological purposes. We should note that there is high consumption of motor oil as a source of heat, for hot water, for the production of pressed fodder, etc. In each individual case, we must calculate whether, given the foreign (not domestic) price of motor oil, its use is still profitable (e.g., production of pressed fodder, considering the quality of other types of fodder).

Generally, we must say with respect to motor oil consumption that its domestic price does not reflect its relationship to other types of fuels, that it distorts the view of its effective utilization, and invites a tendency to ignore conservation in its use.

3. As soon as possible we must halt the rise in light and heavy heating oil consumption for electricity and heat production, and soon thereafter begin to limit their use throughout the industry. Production of electricity and heat by means of fuels whose price is several times higher than the price of domestic fuels, is obviously counterproductive.

This is one of the complicated ways of resolving the problem. Part of the answer (as in changes in the power source in transportation) doubtless

lies in the construction of nuclear plants and their production of electricity. After all, in the growth structure of primary energy sources entering the national economy, the growth of nuclear-produced electricity will be of ever increasing importance. While in 1971-75 oil alone represented almost two thirds of the overall increase in domestic use of primary energy, in 1976-80 it still represented about one third. However, in the coming 5 years its increase will represent roughly only one tenth of the overall consumption of primary sources. In contrast, nuclear energy which in this five-year plan is about one tenth, will in the next 5 years represent almost half of the overall increase in primary energy consumption. It is because of this that corresponding transformation (direct and indirect) of this increase in usage must be found.

What then is of primary importance?

--reduce production of electricity in all plants which depend on heating oil, to gradually correspond to the growth in nuclear energy production, that is, transformation, the implementation of which is relatively easy. As a result of this change, we must achieve an absolute lowering of heating oil use.

--however, to turn a portion of the increase in primary sources gained by nuclear process into heat is a more difficult transformation with respect to both structure and location (excepting a relatively small portion intended to supply heat in the vicinity of nuclear power plants). Several alternatives are possible, the individual advantages of which must be tested, but each of them can prove useful to some degree.

a) the simplest way would be to use electricity from nuclear plants for direct heating of, for example, family houses or installations of the tertiary sphere. This would be best with respect to the environment, and acceptable in terms of energy distribution. The converse of this could be using the increased production of electricity from nuclear plants to further lower production in traditional coal plants, thus reducing the consumption of coal. Low-quality brown coal made available in this way can be used in heating plants and, assuming that the engineering industry produces even smaller boiler units for effective use, we can gain heat for even smaller living and other areas.

b) somewhat harder and governed by location is the possibility of transition of condenser electric plants to thermal operations. This can be advantageous where a major overhaul has already been deemed necessary, where there is potentially large consumption in industry and communal housing, and where the distribution is linked to installation where obsolete heating oil equipment can be replaced.

Generally speaking, it will apparently be necessary to envisage that it will not be possible everywhere to renew obsolete heating and adapter equipment using heating oil. Given the fact that import of expensive oil will decrease in the future, it will be necessary to use the cracking

process; consequently, there will be a drop in heating oil sources and much of the existing equipment will have to be reconstructed. Possible replacements can be provided by some of the above-mentioned methods; in exceptional cases it may be possible to use natural gas.

The cost of primary energy sources needed to form a unit of national income must be purposefully regulated. Their tendency to rise will continue in domestic, but especially in foreign imported sources. Limiting this tendency in brown and black coal, and effectively managing fuels in nuclear plants, must be one of the most important goals of the overall fuels and energy policy. But most of all, we must limit consumption of the most expensive primary energy sources, namely oil and oil-related products, in the transformation of the energy complex. Burdening national revenue with these expensive sources is the same as not having any formation of national income at all. And this is the more serious the slower the formation of national income becomes.

Given the high price of fuels, energy, and raw materials, the primary concern throughout our national economy must be in their conservation and maximum effectiveness in utilization. This is even more important when we consider the fuels and energy situation in the whole country. It is for this reason that we are preparing a special, targeted state program for fuels and energy conservation. The main thrust of this program must be directed at the largest possible savings in oil and oil-related production. Moreover, we will have to learn to utilize more efficiently that portion of primary sources which will then enter the reproduction process. All products, be it foodstuffs, textile, glass, footwear, engineering, construction, or metallurgy, every one of them contains primary energy which costs us dearly in labor and funds. To some extent, we can even claim that virtually the same amount of energy is expended on a bad product as on a good one, on a technically obsolete one or one which is modern in every respect. The point is, however, that the good, technically flawless product can be profitably sold on the domestic or foreign market, which balances the cost of the primary energy which helped to produce it.

It must be the concern of the national economy as a whole and of all levels of management to economize in fuels and energy, to utilize them effectively in the course of the production cycle. Only then will the country have a sufficient supply of fuels and energy to make sure that we produce excellent, high-quality merchandise. Only in this manner can we cut the Gordian knot of primary energy sources, and overcome its limiting force.

Rationalizing Consumption

Prague PLANOVANE HOSPODARSTVI in Czech No 7, 1980 pp 7-10

[Article by Karel Houdek, State Planning Commission]

[Text] In the Directive for Economic and Social Development in the CSSR during 1976-80, the 15th CPCZ Congress decreed more effective management

and valuation of all types of fuels and energy, raw and other materials, and the reaching in industry of 2 to 2.5 percent annual savings in fuels and energy. To accomplish this task the CSSR Government adopted resolution No 123 of 13 May 1976, according to which respective ministers ensure, in the specifications of the state plan, implementation of rationalization measures, and thus guarantee, within the ceilings of the industrial branches, savings of 10.4 million tons of standard fuel [tmp].

These savings are being achieved. It is anticipated that their volume in industrial branches will be more than 10 percent higher. Moreover, since 1978, the kraj national committees have been tasked in this direction and savings there are expected to reach 380,000 tmp. In addition, the state program of rationalization of energy and fuels consumption, established long-term concepts of lowering energy demands in the Czechoslovak economy by setting up regional mechanisms, especially in the manufacture of energy-consuming products. These measures deal primarily with accelerating the introduction of semiconductor technology in high- and low-tension electric operations, better utilization of secondary energy sources, modernization of energy-consuming equipment, rationalization of electricity consumption in lighting technology, regulation and reduction in the use of heat and utility hot water in apartment and communal housing, and reduction in heat losses caused by faulty insulation of buildings.

Despite certain progress in lowering energy demand in our national economy, we cannot be satisfied with the results achieved. Completion of the process of replacing mercury regulators by those made of silica is suffering from delays, we have not fully met the needs of semiconductor welders, nor have we ensured to the needed extent the production and application of high-tension semiconductor technology in the regulation of industrial motors, and we have delayed delivery of thyristor regulators for both industrial motors and transportation. Manufacture of measuring and regulating instruments for heating systems intended for complex housing construction operations, does not fully meet the need.

The above-mentioned facts are partially reflected even in the structure of the fulfillment of the rationalization measures plan. They do not, howevery, fully explain certain negative trends which, in achieving savings in fuels and energy, are clearly evident, especially the high percentage of small rationalization measures, growth in the share of operations where savings in fuels and energy are merely an accompanying feature, and the relatively low percentage of important operations which are achieving measurable saving in fuels and energy. This, together with the fact that, for the purpose of saving over 500 tmp, or 1,000 MWh, the branches are spending 0.5 to 1 percent of their overall investments, would indicate insufficient appreciation of consumption rationalization in fuels and energy in the investment and economic policies of the industrial branches.

The future outlook for the Czechoslovak fuels and energy inventory, which relies on its own geological reserves of fuels, a realistic forecast for

nuclear energy development, and import of fuels and energy sources, indicates the need for fundamental changes in branch approaches to resolving the problems of fuels and energy conservation. Without substantial intensification of the rationalization process aimed at maximum economic performance with minimized fuels and energy consumption, the fuels and energy inventory will become a limiting factor in national economic development. Acceleration of the conservation process in energy demand must be initiated even now, in 1980, and fully implemented during the Seventh and Eighth Five-Year Plans. This task should be understood as part of complex economic relationships and must be implemented in all branches of the national economy.

An important prerequisite for the accelerated pace of lowering energy requirements in the Czechoslovak economy, is better utilization of fixed production assets. Their low utilization is one of the causes of insufficient economic performance. Yet, buildup of fixed assets, the cost of which rises along with their lower utilization, itself ties up considerable capital investment and consumes energy sources. Due to ceilings in capital investment and construction assets, it is impossible to maintain production potential at the most advanced world level, which further reduces economic performance and, at the same time, raises energy demand per production unit.

Among important conditions on which success depends in a dynamic development of supplying the Czechoslovak economy with fuels and energy, we must include:

--modernization of aging energy-consuming equipment which will decrease standard fuels and energy consumption for corresponding production;

--maximum utilization of secondary energy sources which, given the shortages in the primary sphere, represent a potential reserve in the Czechoslovak fuels and energy inventory (construction of incinerators, etc.);

--lowering material demand of the Czechoslovak economy, especially machinery, outfitting, and construction;

--substantially increasing the technical level of a number of our products so that their technological and economic parameters become comparable with products of the most advanced countries. This, in the process of international exchange, will bring about their better reassessment and, at the same time, in most cases also reflect their lower operation consumption of energy in their production.

An example of this type is the following survey of excavator production where the new model KU 800 offers only slightly better performance than the K 800, yet the new model has substantially higher operational weight and is almost six times as expensive:

Excavator designation	Theoretical performance m^3/hr	Theoretical performance per 1,000 m^3/yr	Actual performance per 1,000 m^3 from	Actual performance per 1,000 m^3 to	Op. weight tons	Price mil korunas
E 25	160	1,380	800	1,200	110	0.8
E 302	280	2,400	1,000	1,250	110	1.0
K 300	480	4,150	1,500	2,000	600	7.9
RK 400	480	4,150	2,000	3,300	800	21.5
K 800	1,200	10,300	3,500	6,000	1,315	19.8
KU 300	800	6,900	2,000	2,600	1,050	25.0
KU 800	3,000	25,850	6,000	7,800	3,800	115.0

Resolution of the problems of maximum effectiveness in the use of energy has, due to the more difficult conditions in securing fuels and energy, become a global concern. It is even part of the targeted long-range programs of economic cooperation of the CEMA member states, which deal primarily with problems of lowering fuels and energy consumption, development and perfection of new technological processes, decreasing energy losses in all branches, and maximum utilization of the expensive energy sources.

An important step toward implementation of accelerated decrease in the energy demands in Czechoslovak economy during the Seventh and Eighth Five-Year Plans is the elaboration of the long-term programs of consumption rationalization, savings, and utilization of all types of fuels and energy, as part of the targeted state program. The applicable CSSR Government Presidium resolution No 240/1979 directs, among other issues, the following in this matter:

--achieve lowering of energy demand in Czechoslovak economy through the implementation of concrete measures which will allow savings in 1985 of at least 11 million tmp, and in 1990 at least 25 million tons,

--in the development of iron metallurgy, eliminate increases after 1980 in the overall volume of technological consumption in fuels and energy,

--manage fuels and energy consumption in the nonproduction sphere at roughly the same pace as that of the overall domestic consumption of primary energy sources. At the same time, utilize to the maximum local energy sources, especially combustible waste, regulate the pace of development in the use of private cars in consonance with the development of available sources, and guarantee, with lower fuel consumption, necessary facilities in rail transport and, without increasing consumption, in road transport.

The cited government resolution also approved the intent of the targeted state program of consumption rationalization and utilization of fuels and energy, which embraces concrete tasks in securing a trend toward more effective lowering of energy demands in all branches of the national economy.

In the area of improvement, transformation, and in transporting fuels and energy, we are getting ready for the utilization of selected condenser, traditional, as well as nuclear electric plants to supply industry and the population with heat. High savings can be achieved by modernizing the boiler inventory. Through innovation in the branch and distribution networks we will, in addition to cutting losses, also achieve higher reliability in transit and deliveries. Overall, through the implementation of concrete measures in this sphere, we expect to save in 1985 1.5 million tmp/yr, as compared with 1980.

In the metallurgy of iron and nonferrous metals, we can save in 1985 at least 1.9 million tmp/yr. This, however, depends primarily on changes in the technology of steel production, introducing automated systems in blast furnace operations without a cupola, and better utilization of costly energy sources.

In engineering we can save in 1985 600,000 tmp/yr, especially by implementing a program of reconstruction and modernization of the engineering base and measures in the production of casts. The engineering branch has an important role in the Czechoslovak national economy with respect to lowering its energy demand, because it defines in large measure level of value added of metal composition and quality, as well as the energy parameters of engineering equipment used in all the branches. By means of this, it strongly affects both the suitability of our machinery in the international exchange, and the level of energy losses in Czechoslovak economy. Based on preliminary findings, we can count on relative saving of 1.2 million tons of ferrous metal which, computed in fuels, represents about 1.5 million tmp during the period of the Seventh Five-Year Plan.

In the chemical and consumer goods industries, it is possible by introducing new technology and utilizing secondary sources, to achieve in 1985 a saving of at least 1.2 million tmp/yr. In the production of building materials we can, through the introduction of new, modern technology, save 360,000 tmp annually. Considerably higher savings can be achieved by higher production of perfected heat insulation, fiber, and heat-resistant materials and their application in other branches of the national economy. Their volume in 1985 is to reach 1.8 tmp/yr, compared with 1980.

In agriculture and food industry we expect to save in 1985 about 260,000 tmp, primarily through optimum resolution of problems in agricultural transportation, innovation in pressed fodder production, and higher utilization of secondary energy sources.

Economy in all fuels and energy consumption and the program of their relatively higher valuation, is becoming one of the basic prerequisites of successful future development of our national economy and higher living standard of the population.

Consumption of Oil Products Viewed

Prague PLANOVANE HOSPODARSTVI in Czech No 7, 1980 pp 11-17

[Article by Eliska Rohlova, State Planning Commission]

[Text] After World War II, there was a marked increase in Europe in oil consumption resulting from a sharp growth in private automobile travel, air passenger and freight transport and, in the economically advanced countries, the use of oil products in chemical processing. The share of raw materials based on oil for a new branch of the chemical industry--petrochemicals--increased sharply, especially since the early 1960's. Gradually, oil began to replace certain types of traditional sources of fuels because, in comparison with coal especially, it was economically profitable. The result of this trend was that global consumption of oil in the early 1970's reached 3 billion tons per year. As illustration, we can state that in 1973 the share of oil in primary energy sources in the European Economic Community [EEC] was about 63 percent; in Japan, 75 percent; and in the United States, 45 percent (in the United States energy needs are met to a large extent by natural gas). The rapid rise in consumption in the initial economic growth of the developing countries could not be satisfied by traditional sources. It became necessary, therefore, to explore oil reserves which are very demanding in terms of capital investment (North Sea, Alaska, Siberia).

The World Oil Market

Given the trend in oil consumption in the early 1970's, it was estimated that in 1990-2000 the global production of oil would reach about 5.5 to 6 billion tons. This amount was considered the technical and economic maximum achievable and would mean that, after easily accessible sources had been exhausted, there would be a conflict between demand and supply with all the consequences for world economy.

The price of oil until 1973 was, in comparison with other primary energy sources, very advantageous, way below its exploitable properties. In the period when the rate of inflation in capitalist economies rose dramatically, the low price of oil became one of the barriers in the development of the producer countries. The first price increase by the OPEC countries was influenced by the cost of U.S. production and the production cost of the new drilling operations in the North Sea and Alaska. Even though the rise in oil prices was influenced by economic development, its principal impulse is to be found in the political events in the Middle East where roughly two thirds of the global oil supply are produced. Production and marketing of oil in 1973-79 were seriously affected by these events and prompted the producers to institute further price increases.

The advanced capitalist countries which import a large percentage of the oil they need from the Middle East, were unable, due to economic and

technological considerations, to replace it by other raw materials. Acceptable replacements for gasoline, motor oil, asphalt, and raw materials for chemical processing, have not been found.

As already stated, the concrete level of imports after 1973 was influenced by many factors. It was therefore necessary to reduce the inordinate rise in consumption and orient the economy toward other energy sources.

The reaction of the advanced capitalist countries to the changes in the oil market is illustrated in the following table (in millions of tons):

Consumption of Oil Products in Economically Advanced Countries

	1973	1978	% of own oil in 1978
United States	827.7	887.9	54.9
Japan	271.5	262.6	0.2
FRG	151.9	142.7	3.6
France	127.7	119.0	0.9
England	114.4	94.0	56.8
Italy	106.2	99.5	1.5

Where consumption of oil products had not decreased, as shown by the example of the United States, complications arose, the final resolution of which will inevitably lead to a significant reduction in consumption.

Development of Oil Consumption in the CSSR

Oil consumption, which immediately following World War II was practically zero, has since then registered roughly the same upward trend as in other economically-developed countries. In 1970 production based on oil was 10 million tons; in 1975, about 16 million tons; and in 1980 we expect it to be about 19 million tons. The volume growth of oil products in the CSSR made possible development in private automobile travel, public freight and passenger transportation, mechanization of strenuous labor in agriculture and forestry, and use of diesel oil in rail, river, and air transport.

Since, compared to our need, our domestic sources of oil are negligible, we must meet this need by imports almost exclusively from the Soviet Union. In 1978, for example, the Soviet Union provided 97.8 percent of Czechoslovakia's requirements in oil, and this under very advantageous conditions for our economy, using the most effective transport means, namely, the oil pipeline.

Soviet aid to the CEMA member countries in meeting their needs, especially in energy, is documented by the volume of deliveries in 1976-80, within the framework of long-term trade agreements. This involves 375 million tons of oil, 46 million tons of oil products (gasoline, airplane fuel, petroleum, motor oils, paraffin, and others), 88 billion cubic meters of natural gas, and 64 billion kWh of electric energy.

With respect to imports in the next five-year plan, we envisage that deliveries of oil and oil products from the USSR will be maintained at the 1980 level, even though conditions of producing this raw material have changed. New reserves are located in areas with arctic climate and their exploitation is as much as five times as demanding as in conditions of the European part of the USSR, both in terms of capital investment and technology, not to mention the human element. Conditions in these localities are quite different from production in, for example, Saudi Arabia where the cost of producing one barrel of oil is about half a dollar.

Increases in oil consumption by the Czechoslovak economy will essentially be supplied by imports from nonsocialist countries at world market prices. Also, we must be prepared for the possibility that even oil imported under long-term agreement with the USSR will in the future undergo certain price adjustments. This requires a reevaluation of the original plans for the utilization of liquid fuels in the energy industry, transportation, and other branches, and bringing them into harmony with the realistic possibilities of Czechoslovak economic development. The price of oil, as well as its physical sources on the world market, will depend on the course of the energy crisis in the capitalist world, but also on the development of the political situation and events in the Middle East, and possibly in other areas.

Lowering the Growth Rate in Oil Product Consumption

The favorable price development of oil imported from the USSR, especially increased deliveries, enabled us to expand the utilization of all oil products. An overall analysis of oil use shows that the bulk of oil products are used for the production of heat, electricity, motor fuels and asphalts. The most promising and, so far, irreplaceable way of using oil is chemical processing which in the CSSR did not expand greatly until 1977, and will gradually double, following the introduction of the ethylene unit in Litvinov in 1980. The growing consumption of light products for chemical processing (liquid gas, gasoline, petroleum, and gas oil) will be met basically by existing oil sources. Given the fact that oil will become increasingly expensive and that the criteria for effective utilization of oil and petrochemical products, plastics, india-rubber, etc., will be increasingly demanding, we must draw appropriate conclusions regarding their management in all sectors of the national economy.

Utilization of oil byproducts as fuel in the CSSR will decrease in the coming years and will gradually be replaced by other sources. This stagnation in the first phase and decrease in the next, emanate from the global trend caused by the unfavorable price development, as well as gradual curtailment of production because of factors mentioned above.

In the interest of securing needed sources of light products with higher utility value than can be acquired by oil refining alone, the developed capitalist states and most of the CEMA countries have focused on broader

processing of oil through the so-called secondary sources. With the aid of modern technology it is possible to manufacture from residual oil, which so far has been used for heating, high octane gasoline, motor oil and other products needed more than the original raw material. Given the overall stagnation in oil processing, it is only in this manner that it will be possible in the CSSR in the future to lower the consumption in fuels and secure the propellants which are virtually irreplaceable to the extent required by current needs.

Problems of Savings in Propellants

When we consider that buying a million tons of oil from nonsocialist countries represents, at the 1980 price level, about 310 million dollars, it becomes understandable that the Czechoslovak economy must orient itself toward savings in all types of oil products. If we analyze consumption in the course of the Sixth Five-Year Plan, we see that in many respects it developed spontaneously and the trend was not reflecting the new conditions which emerged in the world oil market after 1973. The sharp increase in private automobile travel, and public road, rail, and air transport, was reflected in the growth in consumption of propellants. Considerable increase in utilization was not always sufficiently justified, and in some areas there was uneconomical usage. Nevertheless, until 1978 it was possible to satisfy all these needs without restriction.

Significant annual increases were registered in diesel fuel where, especially consumption for heating and electricity production showed inordinately rapid growth. Given the relatively large difference in price, uncontrolled sale of propellants enabled some socialist industries to heating oils for certain types of solid fuels. Heating oils had been intended exclusively for the purpose of keeping the population supplied with heat.

The trend in the consumption of diesel fuel, which comprises more than 25 percent of the overall amount of processed oil, indicated that without planned regulatory measures in consumption, it will not be possible in future years to guarantee steady supply for all branches of the national economy. For this reason, in approving the 1979 plan, the government decided to limit its consumption by major users. Following evaluation of the first year since the introduction of appropriate ceilings, we can say that, even though the response by users is so far not commensurate with the current price relationships on the world market, the goal of the plan to halt increases in the use of motor oil, was essentially met. Following a period of annual increases throughout the Czechoslovak economy of 6 percent, the trend has been virtually halted.

Regulatory Measures in 1980

In 1980 we must face the existing situation on the world market and be prepared for further intensification of economic measures in the whole structure of oil products. The system of consumption ceilings is being

expanded to the entire socialist sector in gasoline and, in relation to this, the plan also calls for lower consumption of motor oil. With respect to gasoline, this means a substantial curtailment--about 18 percent, compared with 1978--which will require a whole set of rationalization measures in technological consumption and, above all, a considerable reduction in passenger transport in the socialist sector. The consumption of asphalts was also specified in detail in the formulation of the plan. Along with this, related production will be strengthened (as, for example, cardboard and asphalt products) at the cost of not always economical maintenance and reconstruction of road surfaces.

Methods for the Near Future

Lowering of oil product consumption which, following the introduction of regulatory measures, was implemented largely by organizational intervention in the consumption system, should be resolved in the following important areas by means of thoughtful concepts:

--in structural development and quantity of oil-consuming appliances and their modernization;

--in more economically efficient operations using oil;

--in resolving the effects of slower growth of oil product consumption in related branches;

--in preparing systematic measures in management and the rewards program with the aim of lowering the consumption of oil products in absolute terms.

One of the basic tasks is a substantial lowering of the trend in the consumption of motor oil which represents over 25 percent of the overall balance of processed oil. Since the bulk of motor oil is consumed in freight road transport, we must guarantee its rationalization. The basic goal of rationalization measures is to achieve the planned dynamism performance, without any increases in consumption of propellants, tires, and the number of workers. In road transport which includes public transport of the CSAD [Czechoslovak Automobile Transport], plant planned and unplanned transport, and transport of agricultural organizations, we have experienced certain anomalies. Instead of strengthening CSAD public transport which uses 55 percent less propellant per 1 kilometer than plant transport, its share in road transport in 1978 was 5 percent less than in 1971. As a result, roughly 40 percent of all freight and special vehicles today operate outside the framework of statistical monitoring of their performance and utilization effectiveness. This state of affairs is quite unsatisfactory, not only with respect to propellant consumption, but also with respect to management of economic development. It is therefore necessary to search for methods and means which will gradually increase the effectiveness of transport equipment and performance which are now not monitored by the plan.

In order to raise the share of public automobile transport which, from the point of view of social effectiveness is most desirable, we need to focus on the resolution of the following problems:

--division of transport labor in road freight transport between public and plant road transport, along with consistent strengthening of planned road transport;

--increased role of the center in planned development of CSAD public automobile transport;

--intensification of closer targeting of plant transport with the aim of better satisfying transport requirements;

--consideration in all components of automobile transport of the need for a purposeful, more efficient utilization of trailers and semi-trailers by lowering the percentage of unproductive trips (apply sanctions against drivers who ignore the directive on vehicle inspection);

--issuing binding consumption norms for all types of transport equipment;

--allotting available road transport vehicles to those sectors which practice rationalization of utilization;

--rate performance fulfillment, along with savings in propellants, in the system of material incentive in automobile, rail, river, and air transport;

--explore the feasibility of transferring certain road transport operations to river transport.

In accord with the tasks which road transport must perform in the Seventh Five-Year Plan, the Federal Government directed the Federal Ministry of Transportation and central transportation agencies of the republics to prepare a complex program of freight automobile transport for 1981-85, including stabilization, and/or minimum increase in the use of propellants and tires.

In the building industry which ranks among branches with relatively high consumption of propellants, the following has great influence on economizing:

--composition of the vehicle and machine assets,

--technological level of the engineering inventory,

--settling producer-consumer relations, especially in allocation of sources, and economical transport of materials and products.

Replacement of the vehicle and engineering assets is limited by the capabilities of deliveries, both domestic and imported, from nonsocialist

countries. However, because there are shortcomings similar to those in freight transport, it is necessary to focus on their elimination and on raising the effectiveness of operations.

An important source of savings in the branches of the transportation ministries is the settlement of producer-consumer relations where the crux of the problem lies in:

--supply of construction materials from domestic sources;

--optimum earth removal;

--utilization of seasonal free capacities in rail transport.

Since the building industry, aside from its own plant transport, is a branch which in large measure participates in CSAD public transport, it was decided that we should prepare a program to reduce to a minimum the production and transport of clay in the planning and implementation of capital investment formation, so that the extent of production and transport operations would remain on the 1980 level.

Agriculture and the food processing industry are sectors with a distinct character where statistics conducted to date insufficiently define consumption in the allocations needed for setting directions which will be decisive in terms of rationalization.

Based on assessment by the branches, the basic sources of savings in the consumption of propellants for the coming period, lie in the following measures:

--transfer of additional branch organizations to planned plant transport, the relative pricing of which forms the basis for monitoring propellant consumption and organizing savings;

--gradual structural changes in and renewal of the transportation inventory;

--replacement of tractors used for road transport with trucks;

--expansion of the method of sowing without plowing;

--minimizing operations in field work, especially plowing and cultivation;

--economic reassessment of the expected volume of pressed produce and fodder production and its reduction to an economically effective minimum;

--improvement of the technical condition of vehicles through the necessary range of general and medium overhauls;

--ensuring availability of spare parts and batteries.

In addition to rationalization of propellants used by the major consumers, all branches must check on any other utilization of gasoline and motor oil, such as heating, electricity production, needs of certain technology with high energy demand, where it will be necessary to gradually exclude fuels produced from oil and replace them with other sources of energy.

An important share in the Czechoslovak fuels and energy inventory consists of deliveries of light heating oils, low-sulphur oils, and residuals oils, which represent about 50 percent of processed oil. Even though the demands of the national economy in fuels and energy are rising, deliveries of heating oil will remain at their present level during the Seventh Five-Year Plan, and the level in light- and low-sulphur oils will be lower.

At the same time, it is necessary in this period to create conditions in heavy heating oil consumption for its gradual curtailment, especially in electricity and heat production, and thus achieve a corresponding amount of heavy oil derivatives as a raw material for secondary processing into propellants. Current technology in oil processing does not permit us to reduce proposed oil imports while consumption of propellants is rising. It is therefore necessary to decide in time not only on the construction of a cracking unit but, especially, make enough residual oil available for this purpose.

Prospects in Oil Processing

If we consider that by 1975 about a third of all known oil reserves in the world had been exhausted and that since then consumption has significantly increased, the prospect for the branch which processes oil is not optimistic. Even though the share of the OPEC countries in world oil reserves is 59 percent and that of the socialist countries 10 percent, all economically-advanced countries recognize that the supply of oil is not inexhaustible. In addition to measures cutting import, these countries are focusing on research and the search for substitute energy and raw material sources.

In accord with the global trend, the Czechoslovak economy is passing from extensive utilization of sources toward their intensive reassessment. A part of this strategy is also the planned stabilization of oil product consumption, while maintaining the dynamism of economic development, as well as reliance on chemical processing of oil derivatives as the most effective method of oil reevaluation.

As stated in the report of the Presidium of the CZCP Central Committee at its Fourteenth Session in December of last year, "in the past 4 years, there have been further changes on the world markets which--especially the new rise in the prices of raw materials, fuels, energy, and foodstuffs in the nonsocialist countries--we have not anticipated to such a great measure. This development further underscored our own shortcomings in overall performance, effectiveness, slow application of scientific and technological development and, generally, in the adaptability of our economy to more stringent conditions."

In view of the growing difficulties in obtaining the needed quantities of oil and oil products, focusing on more rationalized management and qualitatively higher cost efficient oil utilization, is one of the factors governing a dynamic future development of the Czechoslovak national economy.

NORTHERN BOHEMIA COAL, ENERGY PROBLEMS DISCUSSED

Prague HOSPODARSKE NOVINY in Czech 15 Aug 80 pp 8-9

[Article by Czech Planning Commission Staff Member Jaroslav Vejrazka: "Problems Transcend the Coal Mining Industry"]

> [Text] The Guideline for the Economic and Social Development of the CSSR for the Years 1976 to 1980 emphasized the prime importance of the North Bohemia kraj as the state's fuel and energy base by calling for a total output of 68 million tons of brown coal in the North Bohemia coal basin in 1980. By way of comparison: the mere 28 million tons mined here in 1955 increased by 1965 to 48 million tons, 10 years later to 57.5 million tons and, in the fourth year of the current five-year plan, to a full 68 million tons. This development occurred at a time when coal began to be mined at a depth exceeding 100 meters at times. These exacting tasks raised considerable problems especially in the capital construction sector. The situation put in doubt the fulfillment of the plan by a shortfall amounting to roughly 1.2 billion korunas. Therefore, in the first half of 1978 central organs decided to look into the problems facing the North Bohemia kraj. After analyzing the situation, the governments of the CSSR and the CSR adopted measures for the last 2 years of the five-year plan. In 1979 the situation improved partly and the volume of completed construction projects rose by 10 percent. This can be viewed positively, but the serious situation concerning the filling of the Ervenice corridor persists: the 1978 shortfall was not eliminated. Moreover, the 1979 plan also remains unfulfilled. How will the situation develop in the last year of the Sixth Five-Year Plan?

The Guideline for the Economic and Social Development of the CSSR in the Years 1976-1980 called for finding a comprehensive solution to the deleterious impact of strip mining and the development of the energy base, especially

on the environment. The following facts will shed light on the situation. Two thousand two hundred apartments had to be replaced in the course of the Sixth Five-Year Plan. A number of communities had to be razed to make room for strip mining. The Most corridor was completed to permit the relocation of the rail line, highway, engineering network and the Bilina River to make room for the mining of high quality coal under the old city of Most. This complicated construction project required an investment of roughly Kcs 700 million and the movement of 1.7 million cubic meters of earth. Another important construction project started during the Sixth Five-Year Plan is the relocation of the Trebusice-Chomutov rail line as a prerequisite for continued progress and increased production of the Jan Sverma mine after 1983. This project will cost about Kcs 1.5 billion.

A second very important construction project involves the relocation of the Usti nad Labem-Teplice rail line which will open access to the new Chabarovice mine in the middle of 1982. This relocation will cost about Kcs 1.2 billion. Continued exploitation of the Ceskoslovenska armada mine is contingent on the elimination of the Drinov water works. Replacing it will cost about Kcs 1.1 billion and will require five construction projects.

The most important project under construction is the Ervenice corridor. This corridor is being built by the mining method (uncompacted) by dumping 400 million cubic meters of earth into the more than 100-meter high earth body.

Coal mining and the construction of new power plants in the Sixth Five-Year Plan will require an overall investment of Kcs 5.5 billion, representing one sixth of all contracted construction work on the North Bohemia territory in the Sixth Five-Year Plan.

Further, the Guideline for Economic and Social Development of the CSSR in the Years 1976-1980 calls for starting the production of a pipe extrusion and a pipe finishing plant from special steels at the Valcovny trub a zeleza Chomutov (Chomutov Pipe and Iron Rolling Mills) and for continuing the construction of the petrochemical complexes at the SCSP Chemical Works in Litvinov. Rail transportation capacity must be increased, the lines must be electrified and automated. To stabilize and increase the labor force will require the construction of 53,000 to 55,000 apartments with all necessary technical facilities and services.

The above survey of fundamental tasks reveals that in the North Bohemia kraj the principal aim of the Sixth Five-Year Plan has shifted to capital construction. Therefore, a separate document was prepared to secure financing of the necessary construction work in the years 1976 to 1980 which was approved by the CSSR Government Presidium by resolution No 251/1976 and the CSR Government by resolution No 295/1976.

Protection of the environment was not forgotten and the respective separate document was approved by the CSSR Government Presidium and the CSR Government.

The Results of Intensified Mining

The unfavorable situation in the area of fuel and energy resources began to be felt in our country as long ago as 1976, which led necessarily to an increase in the volume of mining above the original targets set by the Sixth Five-Year Plan. As a result the construction program had to be expanded which in turn required additional capital funds, an increased labor force and additional needed housing construction (the requirement was raised to 58,000 apartments). Proposed measures required to increase the volume of coal mining were adopted by the CSSR Government Presidium by resolution No 215/1977.

In 1976 and 1977 the situation became even more involved as a result of the functional shortcomings of the newly introduced giant diggers especially in the M. Gorkiy mine, which threatened to cause a shortfall of almost 40 million tons of coal. To maintain the volume of coal mines at the required level, the Most, Merkur, Lezaky and J. Sverma mines had to make up for part of the shortfall even at the risk of reducing the lead of overburden removal over the advancing mining front. For example, the Most mine accelerated its stripping progress so markedly that even under the difficult conditions where the old City of Most had to be demolished to permit mining, it produced in 1978 a full 3.3 million tons, compared with the goal of 1.8 million tons planned originally.

In this period in most cases the volume of coal mined increased at the cost of proper technical preparedness of the mines, especially of overburden removal. This also increased the pressure on the removal or relocation of objects which stood in the way of mining progress. Since this fast mining pace was not foreseen, replacement construction was mostly not included in the Sixth Five-Year Plan. A typical example is the replacement of the Drinov water works, where the replacement projects were originally scheduled to go gradually into operation in 1982: today this deadline had to be moved forward to 3 years.

To ensure the output by the Nastup Tusimice mines the relocation of the Chemutov-Prunerov rail line had to be completed ahead of schedule. The measures adopted to increase the volume of mining by shifts within the basic had necessarily deleterious repercussions also on capital construction, specifically on preliminary and project preparation, and on actual construction. Therefore, adequate measures had to be taken also in this sector.

The CSR Government and the Czech National Control Commission discussed the progress report on the fulfillment of tasks in the North Bohemia kraj in the first 2 years of the Sixth Five-Year Plan, as early as June 1978. The evaluation revealed a number of shortcomings, especially in capital construction. It further became obvious that in some sectors the program adopted for the development of the North Bohemia kraj is not continually being fulfilled. All this could potentially have a deleterious effect on coal output, power output, rail and highway transportation and the programmatic targets in developing the territory.

Reacting to this report the CSSR and CSR Governments requested the submission of proposals aimed at improving the situation in the years 1979-1980. The measures proposed were designed to catch up with the implementation of tasks which remained unfulfilled in the first 3 years of the Sixth Five-Year Plan.

The Causes of the Unsatisfactory Situation

An analysis of the situation revealed that the failure to fulfill the plan was due to the following principal causes:

--Unsatisfactory preparation of construction projects in the field and poor design work, especially in the first years of the five-year plan, as compared with the requirements of the capital construction plan. This was why the construction of a number of projects had to be postponed or replaced by other projects. This complicated in large measure the actions of suppliers and customers: suppliers on one hand chose construction projects which suited them, but on the other hand were forced to accept implementation of projects for which they had no proper project documentation. In housing and special purpose construction, for example, poor project preparation constituted an impediment to the full utilization of construction capacities.

--The planned increase in construction capacities was not fulfilled; the necessary shifts of capacities were not carried out, emergency help and worker transfers had to be organized within the enterprises. Construction capacities were not pooled to the extent needed or in the required structure. The expansion of key construction organizations was limited to their own resources in the kraj. Without substantial help from the other enterprises of economic production units they were unable to fulfill the tasks assigned them. The North Bohemia Konstruktiva, whose assigned tasks exceeded by far its construction capacity, can serve as an example.

--The structural reordering of construction capacities was not adapted to the existing needs in a situation where the proportion of repairs and other work is rapidly growing, drawing off building capacities to the detriment of capital construction. This creates a condition where a plan financed with the amount "S" (capital construction, repairs and other work) is being fulfilled while the capital construction plan is now.

--The fulfillment of the plan was also affected deleteriously by the fact that the other oblasts of the state failed to render adequate assistance to the development of the kraj. The national priority of the North Bohemia kraj was recognized only formally. Local interests prevailed in negotiations regarding transfers, assistance ensuring the implementation of project construction work and organizing the recruiting of labor and apprentices.

The concluding of supplier-consumer contracts for 1979-1980 was an indication of the danger that capital construction in the Sixth Five-Year Plan would fall short by about Kcs 1.2 billion.

Measures for Completing the Five-Year Plan

On the basis of the results of the analysis the CSR and CSSR Governments adopted the following measures:

--Raise allocations to construction organizations for the capital construction plan by Kcs 259 million for the year 1979 and by Kcs 324 million for the year 1980;

--Transfer construction capacities from other krajs since the potential to increase capacities in the kraj has been exhausted, and set for specific organizations the volume of transfer needed to implement tasks at specific projects or their autonomous parts. Channel these transfers primarily to projects which are under construction to effect their quick completion;

--Designate beginning with 1979 the volume of work and deliveries for capital construction as a mandatory indicator of the state plan with the indicator of the overall fulfillment of construction tasks serving for orientation purposes;

--Free the North Bohemia Konstruktiva from its obligations in the peripheral oblasts of the basin and transfer these obligations to outside contractors respecting the already prepared project documentation;

--Transfer the Silnice enterprises, which are managed by kraj national committees, from other krajs to work on the construction of a selected highway network to the limit of Kcs 60 to 65 million and designate this construction work as a mandatory task of the state plan;

--Set a limit for the allotment of funds for the construction of housing in accord with the resolution of the CSSR Government Presidium No 184/1976 in order to ensure the establishment of the material production and manpower base for the construction industry in the kraj;

--Increase staff strength of organizations in the kraj under the jurisdiction of the CSR Ministry of Building Construction by 210 workers by a nationwide hiring campaign;

--Assign the capacities of building construction organizations on a priority basis to projects of the fuel and energy base, those designed to improve the environment or projects vital for the continued economic and social development of the oblast. Special attention must be paid to capital investments arising from coal mining needs, the completion of the relocation of the Chomutov-Prunerov rail line, the construction of the Most corridor, and other projects in the city of Most on which the mining progress of the Most mine depend, the temporary relocation of the Trebusice-Chomutov rail line, and the filling of the road bed of the Ervenice corridor. Further, ensure the construction of installations replacing the Drinov water works and the relocation of the Trebusice-Chomutov and Usti nad Labem-Teplice rail lines, and carry out the comprehensive housing construction and special construction projects of the national committees;

--Strengthen project managements by securing experienced specialists and organizers from other krajs to ensure proper execution of the construction work;

--Secure for construction organizations active in the kraj deliveries of trucks, building machines, supplies and assembly of technological installations for comprehensive housing construction on a priority basis;

--Beginning in 1979 assign to individual construction contractors the volume of capital construction work to be completed for the North Bohemia Kraj National Committee as a mandatory task to prevent further increase in the deficit of the national committee;

--Grant preferential wages and special bonuses in socially important construction projects in accord with resolution of the CSSR Government Presidium No 54/1975;

--Monitor construction work progress of selected civilian construction projects undertaken within the framework of comprehensive housing construction;

--Ensure the installation and servicing of fly ash separators and the adaptation of power plants as pollution control measures on a priority basis;

--Erect in 1979 one, and in 1980 three, nature schools as mandatory tasks of the state plan;

--Create a system of control indicators for the assigned tasks to be carried out by workers designated by the CSSR and CSR Government Commission.

Situation after 1979

A year has now passed since the government resolution came into force which makes it possible to assess how their stipulations and principles were complied with.

A basic prerequisite for developing the kraj is improving the quality of capital construction and its preparation by the investor and designer. The respective tasks were being implemented in a situation when the planned yearly increase in the volume of construction work after a long period of nonfulfillment rose from Kcs 220-230 million in years past to Kcs 981 million in 1979. Neither the supplier nor the investor were fully prepared for so exacting a task which therefore was expected to require many operative interventions. In the end the state capital construction plan was only 94.2 percent fulfilled, with the annual gain amounting to Kcs 586 million.

The failure to fulfill the state plan in 1979 had its repercussions on the results of the largest construction contractor on the territory of the North Bohemia kraj, the CSR Ministry of Building Construction, which fulfilled

only Kcs 388 million of the planned increase of Kcs 711 in capital work. Nevertheless, this is the highest increase ever achieved in the territory of the kraj. The main reasons for the failure to fulfill the plan lie primarily within the ministry, but external factors also played a role.

The primary internal cause for the failure was the inability to fulfill the plan in the first quarter when, as a result of extraordinarily adverse weather conditions the construction volume remained at the level of the first quarter of 1978. But the impact of bad weather cannot account for a whole year's result. Even though the Ministry of Building Construction constantly monitored the fulfillment of the plan and exerted pressure on enterprises to raise their goals by specifying output targets, the shortfall was not made up by the end of 1979.

The second principal cause of the failure to fulfill the plan is a shortage of construction capacities of the industrial and engineering construction sector. The planned reorganization of construction organizations has still not been achieved. But attaining a high planned increase of capacities was predicated on shifting construction capacities.

Construction capacities were not shifted for a number of reasons. The key factor was indecisiveness of general managements in making public interest prevail. Subordinate components and later even the general managements failed to abide by the ministry's order, and this undermined the ministry. The pressure for a shift of capacities also encounters artificial obstacles which must be dealt with once and for all by central organs irrespective of whether technology, complicated relations in the handover of completed construction projects, deliveries of materials, or deliveries by subcontractors are involved.

Mining output trend in the North Bohemia coal basin in 1955-1979.

In this connection we also need to mention the negative attitude some regional organs take when it comes to supporting a shift of capacities to the North Bohemia kraj, an attitude which is based on a lack of understanding and the pretext of having to cope with local problems.

One of the principal factors responsible for the failure of the CSR Ministry of Building Construction to fulfill its tasks is also the unstable situation of the Severoceska Konstruktiva enterprise, which is responsible for 79 percent of the ministry's overall shortfall. It appears that even this year no fundamental change in the prevailing situation can be expected without strengthening the enterprise with the best professional and politically most mature cadres from the entire economic production unit. The thrust of the enterprise's orientation and specialization will again have to be reconsidered. It cannot be expected to build everything from apartments to the most complicated industrial projects.

Among the external factors responsible for the failure of the CSR Ministry of Building Construction to fulfill the plan is also the failure of investor ministries to fulfill the planned construction volumes in the amount of Kcs 120 million.

In the course of the year in a number of projects additional time was lost by a delay in investor preparation and delays in handing over project documentation which necessarily affected also the fulfillment of the agreed-upon or set plan. The proportion due to lack of investor preparation amounts to about Kcs 80 million of the overall shortfall.

When the low gains of preceding years and the unfavorable conditions prevailing at the beginning of 1979 and other factors are considered, the increase of construction work in capital construction by 10 percent over 1978 can be considered a plus, even though the overall planned volume remains unfulfilled. The fourfold rate of growth of construction work compared to the mean overall rate of growth in the country testifies unequivocally to the gradual achievement of priority for the North Bohemia kraj.

As in Investments....

One of the objectives of the adopted resolutions was to fulfill the volumes of construction projects designated as mandatory tasks of the state plan especially in construction projects of the fuel and energy base and the respective investments. In assessing the year's results it can be said that the objective was carried out. The mandatory tasks of the state plan were fulfilled by 96.3 percent, even though no preparations were ready for some mining projects (such as homogenizing and crushing installations at the Chabarovice mine) and there was a 10 percent increase in the volume of work assigned over 1978 levels. The builders fulfilled not only the volume of construction, but also performed the material tasks.

In the course of the year the Lovosice coal transfer point, the electrified Usti nad Labem-Vranany rail line and the third track of the Bilina-Ceske Zlatniky line were put into operation; these projects were of considerable help in getting the coal out of the basin. The tasks of constructing power plant fly ash repositories were also fulfilled. Therefore, compared to last year, when power outages threatened, this year's winter passed without problems.

The successful completion of relocating the Chomutov-Prunerov rail line at the end of 1978 enabled the Nastup Tusimice mines to continue mining. Attention also focused on completing the Most corridor, a project amounting to an investment of Kcs 643 million. By opening the new line to traffic on 1 May 1979 the way was fully cleared for continued work in the Most mine, whose advance was blocked by the old right of way.

The construction of the Ervenice corridor and replacement projects for the Drinov water works constitute vital investments connected with mining. The completion of the Ervenice corridor will allow full-scale operation of the Ceskoslovenske armady and Jan Sverma mines. But a very serious situation arose during the filling of the corridor. The North Bohemia Brown Coal Mines organization failed to make up not only the 1978 shortfall, but also the 1979 shortfall. This caused a delay in freeing part of the areas needed for building the rail line, and mainly the relocation of the Bilina River. Failure to free the building site considerably complicates the progress of construction and the work piles up for completion in the last period.

In contrast, the building of replacement installations for the Drinov water works proceeded successfully. The planned tasks were exceeded also in relocating the Usti nad Labem-Teplice rail line, a key project in the basin. The project is being built by Dopravni stavby Olomouc [Transportation Projects Olomouc], which can serve as an example to other contractors not only for the way this contracting enterprise approaches the fulfillment of its tasks on the territory of the kraj and organizes work, but also for its care for its workers and technical cadres.

With the launching of construction of the new theater, the building of the new city of Most entered its final stage. In the course of the year Severografie was completed, two projects which now house Kancelarske stroje [Office Machines], Barum and Obnova; also the Severoceske energeticke zavody (North Bohemia power enterprises) the okres veterinary facility and the Debora establishment started operation.

To enable the uninterrupted advance of the Most mine the premises of the Okres Communications Administration and of Severoceske keramicke zavody (North Bohemia ceramic works) had to be moved temporarily because their new permanent premises were not completed within the deadline. The construction of special purpose projects such as the hotel, the house of culture, the industrial college, the okres library planned for Most were delayed indefinitely.

...and in Housing Construction?

On the whole, if we can be satisfied with the progress of projects carried out for individual ministries, such is not the case with the progress of capital construction for the North Bohemia Kraj National Committee, with a shortfall in construction work for 1979-capital construction of national committees amounting to Kcs 573 million. This again delayed fulfillment of the material program of the Sixth Five-Year Plan. Completing work worth Kcs 420 million, the CSR Ministry of Building Construction failed to deliver the greatest part.

This failure cannot be taken lightly because it recurs each year with serious repercussions for the living environment, especially in the baisin's okreses, where it has a deleterious effect on peoples' lives. All economic managers, but also political workers from other krajs providing construction work for national committees in the North Bohemia kraj, should wake up to this reality.

The only positive factor in 1979 was the improvement achieved in housing construction, where out of 11,018 apartments planned, 10,571 were completed. But the construction of the respective technical and service facilities large behind, with tasks fulfilled by only 64 and 71 percent respectively.

Overall volume of construction work in the North Bohemia brown coal basin done by construction contractors

Volume of construction work on capital construction projects for the North Bohemia brown Coal Basin done by construction contractors

After initial difficulties the situation improved markedly in 12 selected government-managed comprehensive housing construction projects. Of five projects slated for completion, four were handed over completed. The Chomutov shopping center was not completed because of insufficient construction capacity of the North Bohemia Konstruktiva. The change in coal mining prospects in some parts of the basin also changed the housing construction plans. In the course of the year the Nove Sporice site, where by the end of 1979 the construction of 2,500 apartments was to begin, had to be abandoned. An alternative solution had to be found to meet the housing construction plan for 1980 and the subsequent 5 years. An alternative site was found by joint efforts of the Ministry of Construction and the North Bohemia Kraj National Committee. A similar situation also had to be resolved in the Teplice okres.

Throughout the year the construction of housing turned out to be extraordinarily difficult and suffered from considerable shortcomings. Even though these projects are designated as mandatory projects in the state plan, some were not properly prepared and difficulties arose also during construction. This was the case primarily in the building of heating installations, which is the responsibility of the Federal Ministry of Fuels and Energy, and in transportation projects, whose investor is the North Bohemia Kraj National Committee.

Selected highway network projects exhibited the greatest underfulfillment of the plan with only Kcs 77 million spent, of the stipulated Kcs 107 million. Here the unsuitable structure of construction organizations became most manifest as the result of excessive concentration of engineering capacities for the relocation of rail lines which left inadequate resources for the selected highway network project.

In accord with the government guideline, the 1980 plan was also prepared. To plan realistically capital investment was scaled downward on the basis of expected 1979 results. The output potential of the construction capacities of the CSR Ministry of Building Construction and its ability to transfer additional capacities and workers in 1980 were assessed realistically.

With the participation of supplier ministries a survey of the territory and of preparations by investors and designers was undertaken involving all central investors to ensure the implementation of developmental objectives by adjusting the volume of construction work. The survey revealed that the set volumes meet the necessary extent of planned and properly prepared capital construction on the territory of the kraj.

To master the unsatisfactory situation in the construction of civilian projects implemented within the framework of comprehensive housing construction a CSSR Government resolution on the 1980 plan directed the kraj national committees, excepting the national committee of the City of Prague and the North Bohemia kraj, to render assistance by okres construction enterprises in the amount of Kcs 60 million.

The adopted government resolutions, No 273/1978 and No 316/1978, create favorable conditions also in 1980 to ensure the uninterrupted construction of mining and power supply capacities, the establishment of the Czechoslovak uranium mining industry in the Ceska Lipa region, and the construction of power plant fly ash repositories. Attention focuses also on securing funds for emergency investments and investments for housing construction.

BRIEFS

OLEAGINOUS PLANT SELF-SUFFICIENCY PLANNED--Per capita consumption of pure fats in Czechoslovakia, as food, will reach about 25 kg in 1980, approximately 70 percent higher compared with the pre-WW II statistics. In 1936, the percentage of animal fats amounted to 70.2 percent of the total pure fats consumption; the current figure is 58.4 percent. In 1979, the per capita consumption of vegetable oil and fats reached 9.8 kg. During the first four years of the Sixth Five-Year Plan, the average CSSR annual production of oleaginous plant seeds reached 162,000 tons, a 30 percent increase compared with the Fifth Five-Year Plan annual average. Still, in spite of increased yearly production, 60 percent of raw materials for production of vegetable oil and fats have to be imported. The 1980 plan calls for production 240,000 tons of oleaginous plant seeds; of this 190,000 tons of rape, 25,000 tons of sunflower, 15,000 tons of flax and 2,500 tons of soybean seeds. The figure also includes 7,500 tons of poppy seed, mustard seed and other raw materials not processed by the industry producing vegetable oil and fats. Estimated 1985 production of oleaginous plant seeds calls for 287,000 tons, reaching 300,000 tons in 1990 and thus hopefully reducing the current level of exports by two-thirds. [Bratislava ROLNICKE NOVINY in Slovak 27 Aug 80 p 4]

GASOLINE CONSUMPTION--In 1979 a total of 398,000 tons of gasoline for cars were sold in Slovakia; 58.3 percent of this was sold to private car owners. The percentage is expected to increase to 62.7 percent in 1980. At present 290 gasoline stations are operating on Slovak territory; the average distance between stations is less than 20 kilometers. This year socialist organizations are expected to save a full 25 percent of the 1978 level of gasoline consumption, resulting in consumption at the 1971 level. Private car drivers are expected to save enough gasoline to reach the 1978 consumption level. Slovakia now has no gasoline stations on the super highway; stations are planned for sections between Bratislava and Lamac, and between Sekule and Zelenec. The realization of this plan depends on the financial means allotted by higher bodies. Bratislava now has 15 stations, which is not enough; the target of having 30 stations is being constantly delayed due to the lack of finances, and only 10 new stations at most will be built in Bratislava during the seventh 5-year plan. [Bratislava SMENA in Slovak 9 Aug 80 p 3]

SUGAR BEET HARVEST--In the Czech Socialist Republic sugar beet was sown this year on more than 157,000 hectares; 45 percent of this acreage was sown with genetically one-sprout seeds. But crops had to be plown under on roughly 3,500 hectares because of late sowing, dry weather in May and excessive moisture in June. At present 26 percent of the acreage is in very good condition; 38 percent in good condition; more than 25 percent satisfactory, and more than one tenth of the acreage is in bad condition. The largest acreage--4,700 hectares--awash with ground water is in Eastern Bohemia. [Prague PRACE in Czech 12 Aug 80 p 1]

FOREST CALAMITY--Current timber losses by natural causes in the CSR forests are the worst experienced since WW II. This year's damage amounts to about 80 percent of the annual lumber production. Most of the damage is in forests of the South, West and Central Bohemia Krajs. Because of the huge amount of accumulated timber, its removal from forests is not expected to be completed prior to 1982. Organizational and individual help in form of work brigades is needed in reforestation of these areas. About 1.5 million cubic meters of wood is available in certain areas, where the populace is offered firewood and lumber through self-help. [Prague SVOBODNE SLOVO in Czech 9 Sep 80 p 4]

TRUCKS FOR MOROCCO--The AVIA Enterprise of Prague has built the first series of 50 of its A-15 trucks for Morocco, with the second series to follow in September. The trucks are adapted for use in rough terrain and hot climate. [Prague VECERNI PRAHA in Czech 21 Aug 80 pp 1, 2]

BUDGET ACCOUNTING FOR 1979 PUBLISHED

West German Commentary

Bonn INFORMATIONEN in German No 13, Jul 80 pp 11-13

[Background' report by FRG Ministry for Inner-German Relations: "GDR Budget Accounting for 1979 Approved by People's Chamber." The official budget accounting text as published in East Berlin NEUES DEUTSCHLAND follows this commentary]

> [Text] On the occasion of its 11th session (3 July 1980), the GDR People's Chamber approved the Council of Ministers' budget accounting for 1979, as presented by new Finance Minister Werner Schmieder. This accounting of the state budget was once again published by the SED organ NEUES DEUTSCHLAND -- as was done for the first time last year with the 1978 budget. The volume of the budget (including social insurance) rose in 1979 to M 140.6, which means an increase of about 6 percent. To be sure, the budget plan for 1979 called for a volume of only M 137.4 and thus was exceeded by about 2 percent. Bycontrast, the rise in national income planned for 1979 could not be reached; it was around 4 percent.

The budget volume had already expanded at a greater rate than national income between 1976 and 1978. The government sector expenditure share -- or the share of the state budget in the GDR's national income or national product -- was increased from 79.9 percent (1976) to 83.9 percent (1979). This points up a growing direct influence by the state on the distribution and utilization of the national product.

Revenues

Revenues from the GDR's total public budget (= income of the central government, the bezirks, kreises and municipalities) amounted to M 125.7 billion last year. Including employee social insurance contributions and the share paid by employers (VEB's, combines, cooperatives, state

administration) in the amount of approximately M 14.9 billion, GDR state and social budget revenues totaled M 140.6 billion.

Compared to 1978, the GDR treasury obtained a 6.3-percent increase in pure budget income in 1979 (excluding revenues from social insurance contributions). Within the current five-year plan period (1976-1980), this figure constitutes the highest increase thus far for actual revenues in a single year. The rates of increase for state income amounted to 2.5 percent in 1976, 6.1 percent in 1977 and 5.7 percent in 1978.

The main sources of GDR budget revenues are the compulsory payments by state economic organizations (VEB's, combines, VVB's /associations of state enterprises/) and banks. These enterprise taxes are comprised primarily of payments by production organizations and banks out of net profits earned (= profits taxes) as well as production fund and inventory taxes (= taxes on working capital). In 1979, approximately 44 percent of all state income (excluding social insurance revenues) derived from tax payments by enterprises and banks.

The second most important source of revenue for the state budget in the GDR is the direct or indirect taxation of the public. In 1979, one-third of the revenues came from taxes on private income and from the tax burden on consumer expenditures by private households. Unique to the system of procuring revenue for the state in the GDR is the fact that the emphasis in tax contributions required of the citizenry lies with (invisible) indirect taxes -- in other words, with the sales and consumption taxes that are figured into the prices of consumer goods. The levying of sales and consumption taxes in 1979 brought the state about 28 percent of its total income. On the other hand, revenues are comparatively small from the tax on wages and salaries and from the income tax for "free-lance members of the intelligentsia" on income derived from independent work. Their contribution to the procurement of funds by the state has for years amounted to a mere 5 percent of the total tax bill (M 6.6 billion).

By contrast, private artisans in the GDR pay heavy taxes. In 1979, the state treasury took in revenues of around M 2.7 billion from payments made by this group of taxpayers. This amounts to a somewhat greater than 2-percent share of the total revenues of the GDR's unitary budget (excluding social insurance contributions). Thus, for example, the taxes paid by private artisans are twice as high as the agricultural taxes paid to the state by "socialized agriculture" (LPG's and VEB's together).

The tax payments of private artisans are also considerable when compared to the tax revenues which the treasury receives from all artisan producer cooperatives (PGH) and the various other types of "socialist cooperatives" that exist: For instance, the private artisan enterprises pay not much less in taxes than do the collectivized artisan trade, the consumer cooperatives and all other forms of cooperatives (excluding LPG's) combined,

which together contributed the sum of approximately M 2.9 billion to the state treasury in 1979.

Expenditures

Heading the list of expenditures in the budget accounting are those for social insurance, with M 27.4 billion (+ 3.0 percent). Excluding social insurance expenditures, but including supplements credited to social insurance, the volume of expenditures amounts to M 126 billion (+ 7.0 percent).

The importance of investments and outlays for science and technology, repeatedly stressed by the GDR government and media, is not reflected in the budget accounting. On the contrary, the development of expenditures in this sector is below average; there was even a further absolute decline in such investments financed out of the state budget in 1979. They amount to M 6.1 billion, after having been pegged at M 6.5 billion in 1978 and even M 7.0 billion in 1977.

Subsidies

Approximately half of the indirect increases in income granted to private households out of the state budget in 1979 (in the form of setting prices and rates below the costs needed to produce goods and services) were used to cut the cost of foodstuffs. About 28 percent of the subsidies that benefit the public directly were needed to bring down retail sales prices for sociopolitically important goods, to cut the purchase price for household fuels and to fix the rates for gas and electricity at low levels. Among the many industrial goods for which the government grants to the public retail prices that are below the actual cost of manufacture are baby clothes, clothing for young children, children's shoes, baby carriages and strollers, books, newspapers and pharmaceuticals.

The largest increases in budget subsidies since 1975 are the additional payments for the combined entry entitled "Price supports for industrial goods, household fuels and energy rates." The GDR government was able to get by with subsidies amounting to about M 1.2 billion in 1975, but it was already costing the government the sum of M 2.9 billion in 1978 to maintain the stability of ultimate consumer prices for this group of goods. Compared to 1978, an additional amount in the neighborhood of M 1.5 billion had to be spent in 1979 to assure stable prices and rates in this sector.

The most important reason for this increased need for subsidies is the tremendous rise in the cost of producing electricity, gas and household fuels. And these increased costs are in turn a direct result of the price explosion affecting raw materials and energy sources (especially petroleum) on the world market and in internal CEMA trade.

Revenues, Expenditures Listed

East Berlin NEUES DEUTSCHLAND in German 4 Jul 80 p 3

[Official text of "Budget Accounting for the Year 1979 -- Important Revenues and Expenditures of the State Budget"]

[Text] I. Revenues

	In millions of marks
Total Revenues:	140,633.4
Revenues from state enterprises, combines and VVB's:	
Payments from production fund taxes and inventory taxes	16,815.9
Payments from net profits	32,882.7
Payments from product-related taxes	34,975.8
Payments by banks	5,271.5
Taxes on agriculture	1,394.3
Revenues from agricultural facilities, especially state veterinary services	458.5
Land use fees	338.4
Revenues from water use fees and other revenues from water management directorates	165.4
Revenues from:	
Artisan producer cooperatives and other socialist cooperatives	2,859.8
Private artisans and tradesmen	2,665.5
Taxes on the wages of workers and salaried employees	6,586.5
Revenues from research by the Academy of Sciences as well as by advanced schools	406.2
Rental revenues of municipal communal housing administrations	177.4

Revenues from state educational institutions, particularly for room and board and fees	671.6
Including:	
Public education	368.9
Advanced and technical schools	267.0
Vocational training	5.8
Adult continuing education	29.9
Revenues from state health institutions	6,236.3
Including:	
Payment for health services through social insurance	5,037.4
Revenues from pharmacies and orthopedic stations	751.5
Other revenues, such as those from laundry services, contributions by parents to day-care centers, defrayal of costs at recreation centers and nursing homes	447.4
Social insurance revenues	14,902.8
Including:	
From the shares contributed by enterprises, state organs and institutions, cooperatives	8,478.4
From worker contributions	6,424.4
Revenues from state cultural, recreational and sports facilities as well as youth facilities	615.9
Including:	
Culture	453.1
Recreational and sports facilities	137.7
Youth facilities	25.1
Radio revenues	111.9
Television revenues	381.0
Revenues from communal measures and services	162.2

Fees and other administrative revenues of the state apparatus and economic management organs	261.5
Municipal taxes	536.1

II. Expenditures

	In millions of marks
Total Expenditures:	140,222.6
Budget funds for science, technology and research facilities	2,306.1
Including:	
Funds for science and technology in state enterprises and combines	1,000.7
Funds for science and technology in the field of agriculture and forestry	313.5
Funds for research and development in state institutions and facilities	991.9
Including: Research expenditures of the Academy of Sciences	480.6
and of the advanced and technical school system	399.7
Budget funds for research in the social sciences	176.5
Budget funds for financing investments	5,614.9
Expenditures for the maintenance and repair of transport routes (roads, waterways, railways, seaports, inland harbors and airports)	3,024.3
Product-related price supports for raw materials and base materials	5,180.0
Price equalization fund for industrial enterprises for the temporary equalization of effects of scheduled industrial price changes	1,065.8
Subsidies to agriculture for soil improvement, investment credits, product-related price markups and other measures designed to encourage production	2,341.0

Product-related price supports for means of production for agricultural enterprises	5,156.0
State expenditures for agriculture and forestry, such as veterinary medicine, crop protection, special schools, exhibitions	581.3
Expenditures for recultivation measures	15.9
Expenditures for water management	556.8
Expenditures for housing	6,708.4
Including:	
Expenditures for new housing construction, including new social facilities	1,865.5
Expenditures for the modernization of residential structures	230.0
Construction repairs on existing housing	1,053.3
Expenditures for administering and managing existing housing	1,553.9
Credit allowance for young married couples, as well as interest deductions for the use of credits	188.1
Interest on and retirement of investment loans for new housing construction	1,817.6
Price supports to assure stable prices for basic goods and rates for the public	15,726.8
Including:	
Food	7,721.8
Industrial goods	4,415.2
Long-distance and local passenger fares	2,674.8
Drinking water and sewage treatment fees	676.3
Repairs and services	238.7
Expenditures for minor price adjustments and seasonal measures	161.8

Expenditures for education	9,674.8
Including:	
Expenditures for public education	6,799.3
Including:	
Instructional and learning aids and toys	186.7
Meals for schoolchildren and younger children	866.3
Transportation of schoolchildren	141.5
Advanced and technical schools	1,984.0
Including:	
Scholarships	455.2
Expenditures for boarding schools	108.1
Meals for students in dining halls	105.0
Vocational education	797.1
Facilities for continuing adult education	94.4
Expenditures for health and social affairs	9,259.4
Including:	
Expenses for hospitals	3,280.8
Expenses for polyclinics, out-patient clinics and general practices	1,832.6
State aid to minor dependents and maternity benefits	1,363.2
Supplementary payments to large families	83.0
Expenses for recreation centers and nursing homes	522.4
Expenses for providing the elderly with housekeeping services and noon meals	173.2
Social insurance expenditures	27,375.3
Including:	
Pensions	14,383.8
Sick benefits	3,598.3
Pregnancy and maternity benefits	688.0
Aid to mothers for paid leave (baby year)	259.8
Expenditures for youth facilities, including tourism	100.0

Expenditures for culture	1,599.1
Expenditures for sports facilities	328.2
Expenditures for recreation and vacation services	392.9
Subsidy for foreign tourism	273.6
Municipal measures and services; for example, street lights, trash pickup, maintenance of parks and open space	819.7
Expenditures for radio	197.8
Expenditures for television	472.4
Expenditures for state apparatus and economic management organs	3,719.1
Civil defense and fire protection	114.0
Expenditures for national defense	8,674.0
Expenditures for public safety, the administration of justice and securing the state border	3,474.0

DEVELOPMENT OF INLAND WATERWAY SYSTEM REVIEWED

East Berlin PRESSE-INFORMATIONEN in German No 97, 15 Aug 80 p 6

['Facts and Figures' report by Press Office, Chairman, GDR Council of Ministers: "The Inland Waterways of the GDR"]

[Text] Today, the inland shipping of the GDR has at its disposal a waterway system with a total length of 2,546 kilometers. Of this, 1,680 kilometers can be navigated by ships having over 800 tons of capacity. The most important waterways are the Elbe, with a total length of about 1,300 kilometers, of which 566 kilometers either lie within the GDR or form part of the national border with the CSSR and the FRG, and that section of the Oder, 161.7 kilometers in length, which forms the national border with the Polish People's Republic. In addition to these there are connecting waterways between the Elbe and the Oder such as the Elbe-Havel Canal and the Lower Havel Waterway. Other important waterways are the Mittelland Canal, the Hohensaaten-Friedrichshaler Waterway, and the Saale. The waterway system also includes rivers such as the Unstrut, the Elde, and the Lusation Neisse, which however have only minimal significance for shipping.

An example will give an idea of the extent of the waterways in the GDR. The distance along the waterway between Eisenhuettenstadt on the Oder and Niegripp on the Elbe amounts to 255 kilometers. Given an average traveling speed of 8 kilometers per hour and taking into account the times spent passing through locks, about 37 hours of travel are needed for this journey.

For decades now, extensive regulating measures have been carried out with respect to the rivers in the territory of the GDR. Back in the 19th century, interconnections had already been established between the individual river and stream systems through the canalization of rivers and the cutting of canals. The completion of the interconnections between the Elbe and the Oder, which include the Elbe-Havel Canal, the Havel-Oder Waterway, and the Spree-Oder Waterway, caused traffic along the waterways to increase substantially.

The founding of the GDR ushered in a new stage of development for the inland shipping. First of all, the destruction caused by World War II had to be eliminated in order for inland ships to be able to run again at all on the waterways of the GDR. Numerous bridges had been blown up, and a large proportion of the vessels of the transport fleet had been sunk and thus blocked the waterways. Locks, weirs, embankments, levees, and so forth showed extensive damage and had to be restored. After the worst of the wreckage had been cleared away by an enormous effort, the working people of the waterways administration set about the systematic reconstruction of all facilities. By the beginning of the 1950's, the 32-kilometer-long Havel Canal had already been built, thus establishing a beneficial link between the Lower Havel Waterway and the Havel-Oder Waterway.

On the Elbe, the water depth amounts to between 2 meters and 2.40 meters at medium water level. It is primarily dependent on the supply of water from the respective catchment basins of its tributaries. In May and July of this year, shipping had to be banned because the river overflowed its banks, became difficult for the navigation of ships, and was flowing too fast. In such cases, the clearance heights under the bridges are too small in some places.

In dry periods, the water depth can fall to values ranging around 1.50 meters. In the exceptionally dry year of 1964, the smallest depth was only 65 to 80 centimeters between the CSSR border and Boizenburg. With normal water levels, individual vessels 80 meters in length and 11 meters in width are allowed on the Elbe between Schoena and Boizenburg. Barge trains can have dimensions of up to 190 meters in length and 25 meters in width, depending on the water level and on the section of river. The depth conditons of the Oder are similar to those of the Elbe. Depending on the water level, loaded barge trains with a length of 156 meters and a width of 11 meters can be operated on this river.

Canals and canalized stretches of river have essentially constant depths. Thus, between the capital of Berlin and the Elbe, by way of the Lower Havel Waterway and the Elbe-Havel Canal vessels with a draft of 2 meters can be run continually. Between Berlin and Hohensaaten, the Havel-Oder Waterway is suited for individual vessels having a length of 67 meters and a width of 8.20 meters. The depth comes to 2 meters here. Barge trains with a length up to 135 meters and a width up to 8.20 meters are permitted on this waterway.

The connection between Berlin and Eisenhuettenstadt by way of the Spree-Oder Waterway can be passed through by individual vessels with a length of 67 meters and a width of 8.20 meters. For barge trains, the permissible size is 123 meters in length and 8.20 meters in width. The designed draft is 1.85 meters, and for machine-driven vessels it is 1.75 meters. The other principal waterways have similar proportions.

All the canals and canalized stretches of river have locks and ship elevators. The most important and at the same time most interesting structure here is the ship lift at Niederfinow near Eberswalde. This lift overcomes a height difference of 36 meters. The second ship elevator is located at Rothensee near Magdeburg and overcomes a height difference of between 11 and 18.50 meters, depending on the water level of the Elbe.

Numerous locks are located along the individual waterways. The Brandenburg Lock is one of the most extensively used of all large locks, having two coffers 210 and 170 meters long. The twin chamber lock of Eisenhuettenstadt has two coffers 130 meters long and 12 meters wide. The height difference between the upper and lower water level is between 9 and 14.2 meters, depending on the water level of the Oder.

Of course, the GDR's waterways are not restricted to serving as a traffic channel for transport shipping. For example, industry takes coolant water from them, and agricultural operations partly supply their sprinkler systems with water from the rivers and canals. In the summer months, many citizens use these waterways for outings with the White Fleet or for water sports. Then there is a lively bustle above all on the Mueritz-Elde Waterway, the Mueritz-Havel Waterway, and the Upper Havel Waterway. In these areas, numerous working people find relaxation every year.

CROP, WEATHER REPORT PUBLISHED FOR JUNE 1980

East Berlin FELDWIRTSCHAFT in German Vol 21 No 8, Aug 80 p 384

[Article by Dr D. Krumbiegel, GDR Meteorological Service, Central Weather Bureau, Potsdam]

[Text] The Weather in June 1980

Subnormal air temperatures at the beginning of the month and after 18 June included a warm weather period. Rain was unusually frequent and especially abundant in the northern GDR. There was not much sunshine.

During the first two 10-day periods daily average air temperatures only on a few days deviated by more than 3 K from normal values. Between 22 June and the end of the month anomalies of usually between -3 and -5 K occurred. The weather period that was too warm generally brought in daytime maxima above 20°C. Values around 25°C were recorded widespread on 5, 9, 10 and 13 June. On 14 June, maxima went up to 32°C locally. For the rest of the time, maxima mostly ranged between 15 and 20°C, at the end of the month they often even dropped below 15°C. Night ground minima dropped below 5°C only in the first few days of the month (1 June recorded -1°C in the Cottbus area). Thereafter they mostly ranged around 10, and during the third 10-day period between 5 and 10°C. Only the first 10-day period had much sunshine in the northern GDR. The second part of the month was marked by very little sunshine.

Only two days (4 and 6 June) remained completely without rain in the entire area. The rest of the time brought in a lot of rain, with showers predominating. In the second 10-day period the rain was most abundant. Altogether, the northern GDR got more rain than the southern. Frequently there were daily volumes between 30 and 60 mm (Schwerin got 112 mm on 11 June). There were between 5 and 8 days with rain volumes around 3 mm widespread in the second and third 10-day period. Schwerin got the extreme monthly volume of 234 mm (= 442% of the normal value).

Temperature Data for June 1980 according to the Chief Climatological Office, Potsdam

1. Monthly Average Air Temperatures and Deviations from the Norm

Schwerin	15.2°C	-0.4K	Erfurt	14.5°C	-0.7K
Neubrandenburg	15.0°C	0.0K	Leipzig	15.9°C	+0.1K
Potsdam	16.1°C	-0.2K	Goerlitz	15.2°C	-0.4K

2. Mean Precipitation according to Bezirks

Rostock	122 mm	= 235%	Halle	70 mm	= 127%
Schwerin	129 mm	= 235%	Erfurt	99 mm	= 160%
Neubrandenburg	144 mm	= 215%	Gera	92 mm	= 133%
Potsdam	89 mm	= 165%	Suhl	111 mm	= 156%
Frankfurt	107 mm	= 195%	Dresden	84 mm	= 106%
Cottbus	87 mm	= 143%	Leipzig	76 mm	= 121%
Magdeburg	97 mm	= 187%	Karl-Marx-Stadt	76 mm	= 87%

3. Evaporation Potential

Northern Bezirks	60...75mm
Central Bezirks	70...90mm
Southern Bezirks	60...80mm

Soil, Crop and Labor

Toward the middle of the first 10-day period, surface soil temperatures rose to around 20°C. On 18 June the ground started cooling off rapidly. In the third 10-day period surface soil temperatures lay around 15°C. In the subsoil, the warming up period was delayed. There, with the end of the second 10-day period, temperatures dropped down to clearly subnormal values. By the end of the month, from 13 to 15°C were recorded at a 50-cm depth, from 12 to 15°C at a 100-cm depth. Ground water content diminished in the southern plains, widely in the first 10-day period and still locally in the second. Then the ground water level rose strongly everywhere in the third 10-day period, as it had already done before in the northern GDR. Under the turf they recorded at the end of the month at a depth down to 50 cm between 70 and 95% of usable field capacity in ground water in areas that had been heavily soaked. Elsewhere, values were between 40 and 70%. Showers in part were very intensive and then there were considerable runoff losses on ground level. Erosion damage, mud formation and temporary soaking resulted. Soil climatic conditions improved in the course of the first half of the month depending on rain supply. Composting and nutrient mobilization were held up, starting with the end of the second 10-day period, when subnormal ground temperatures were persistent.

The high air temperatures in the first half of the month greatly stimulated growth. Initially, to be sure, that was limited by moisture supplies, mainly for the cultures going through their main growing period. At the same time there was an acceleration in development and a rapid succession of the phenological phases. Starting with the end of the second 10-day period the low air temperatures (daytime averages mostly between 12 and 15°C) and the lack of sunshine then prevented a full utilization of the meanwhile very good moisture supplies. Most strongly disadvantaged were cultures that need a lot of heat, like corn, fruit vegetables and beets. These conditions were advantageous for forage growth, especially grasses, the filling in of potatoes, the grain formation for the winter crop, but also the growth of weeds. The cool and humid weather once again delayed developments which became most conspicuous in the ripening processes. Heavy rains made the winter barley and winter rye turn over, but not too much because of the rather solid stalks. Hail caused local damage. Fungus pests had an easy time.

During the first 10-day period field work hardly suffered from disturbances due to the weather, but then came more and more interruptions because of the rain. The beet crop cultivation had been delayed anyhow (delayed cultivation, slow early growth), and that significantly diminished the time available for labor. Furthermore, the effect of mechanical anti-weeding measures was curtailed. For the forage harvest the high ground moisture content often led to vehicle tracks and required extra tractor power. Starting at mid-month drying conditions became very unfavorable that hardly permitted hay formation and considerably interfered with the preparation of ensilage (losses of nutrients, inadequate dry substance content). Average daily duration of relative air humidity below 70% dropped from 8 to 10 in the first half of the month to from 5 to 7 h in the second. Whereas first there had still been a great need for rain, this was reduced in the course of the second 10-day period, starting in the north. In the third 10-day period only small areas were left in the southern plains that needed extra water. Reservoir and damming areas had to be drained to ensure the trafficability and grazing capacity of the areas and prevent scar damage.

Meteorological Projections for Farming for August 1980

As the June weather was perfect for widespread potatoe rot extensive herbicide measures are of increased importance. In scheduling dates for that one should consider the possible extra growth and harvesting deadlines.

For the grain harvest, due to the introduction of the summer season, there is a one-hour shift for drying operations in the morning and watering the crops in the evening, which should be taken into account in drawing up working plans. Also recommended is recording the duration of rain periods which is more important after showers than the rain volume for the absorption of moisture. For example, when the rain lasts up to 1 h, the moisture gained is between 1.5 and 2.5%, when 2 or 4 h, between 3.0 and 4.0 or between 4.5 and 6.0% respectively.

Crops accustomed to much and easily accessible water will need extra water even in brief rain poor periods.

CROP, WEATHER REPORT PUBLISHED FOR JULY 1980

East Berlin FELDWIRTSCHAFT in German Vol 21 No 9, Sep 80 p 432

[Article by Dr D. Krumbiegel, GDR Meteorological Service, Central Weather Bureau, Potsdam]

[Text] The Weather in July 1980

Subnormal averages in daily air temperatures lasted until the 23th, and subsequently the weather was somewhat too warm. There was a lot of rain, especially in the first two 10-day periods. Sunshine was considerably below normal.

The very cool weather of the third 10-day period of June lasted until the 6th, with from 2 to 4 K subnormal daily air averages. Between the 12th and 22nd it was from 3 to 5 K too cold most of the time. Daytime maxima up to the beginning of the third 10-day period mostly ranged between 16 and 22°C. Starting with the 24th, maxima generally came to from 20 to 25°C, on some days, up to 28°C. At night, ground air temperatures several times dropped to from 5 to 10°C. For the rest of the time the minima mostly stayed around 10 or between 10 and 15°C, at the end of the month, around 15°C. Only between the 23rd and the 27th did the daily duration of sunshine in the whole territory of the GDR amount to from 12 to 15 h. For the rest of the time, sunshine was very poor, still more so in the south than in the north. In circa 20 days less than 5 h in sunshine were recorded widespread.

Only between the 23rd and 27th the territory of the GDR remained absolutely rain-free. For the rest of the time, precipitation fell mainly in the form of showers, which brought regionally very uneven water supplies. Almost on all rain days, local or regional volumes recorded were between 5 and 20 mm. Especially high were the volumes in the first 5-day period (regionally from 15 to 35 mm), on the 21st (Gera Bezirk, Karl-Marx-Stadt Bezirk and Dresden Bezirk, 50 to 85 mm), and at the end of the month (locally 30 to 40 mm, Teterow, 75 mm). At selected stations, total rain periods between 75 and 105 h were recorded (Magdeburg 55 h, Dresden and Karl-Marx-Stadt 135 h). The daily averages of relative air humidity dropped somewhat below the 70% limit only during the brief period when the weather was fine and otherwise mainly ranged between 75 and 90%.

Weather Data for July 1980 according to the Chief Climatological Office, Potsdam

1. Monthly Mean Air Temperatures and Deviations from the Norm

Schwerin	15.7°C	-1.8K	Erfurt	14.7°C	-2.1K
Neubrandenburg	15.8°C	-1.3K	Leipzig	14.5°C	-3.5K
Potsdam	16.3°C	-1.8K	Goerlitz	15.4°C	-2.1K

2. Mean Precipitation according to Bezirks

Rostock	89 mm = 124%	Halle	87 mm = 124%
Schwerin	101 mm = 137%	Erfurt	79 mm = 105%
Neubrandenburg	100 mm = 132%	Gera	108 mm = 135%
Potsdam	87 mm = 119%	Suhl	134 mm = 166%
Frankfurt	83 mm = 112%	Dresden	151 mm = 162%
Cottbus	111 mm = 146%	Leipzig	109 mm = 133%
Magdeburg	75 mm = 110%	Karl-Marx-Stadt	162 mm = 162%

3. Evaporation Potential

Northern bezirks	55...70 mm
Central bezirks	50...65 mm
Southern bezirks	45...60 mm

Soil, Crop and Labor

Up to the start of the third 10-day period, surface soil temperatures mostly ranged between 15 and 18°C. After mid-month, often values below 15°C were temporarily recorded. In the third 10-day period up to the 26th and 27th, the soil got much warmer, by from 4 to 7K in the north, from 6 to 9K in the south. Then values dropped to around 20°C by the end of the month. In the subsoil, no noteworthy temperature drop could first be found. Starting with the middle of the third 10-day period it warmed up. By the end of the month, 17 to 19°C were recorded at the 50 cm depth, and 15 to 18°C at the 100 cm depth. All the rain kept the ground very moist both in the subsoil and surface soil, between 70 and 90% of usable field capacity. Somewhat lower values were recorded at the loess areas of the bezirks of Magdeburg, Halle and Erfurt. In areas where it had rained a great deal, ground water temporarily reached field capacity values. The conditions were mostly unfavorable to vegetation. Only in the third 10-day period, temperature conditions improved. So much dampness in the soil interfered with the air budget and led to crowding. And when in addition then there were heavy rains, erosion and puddles occurred, and floods in low lying areas. The condition of the plots was such that, especially in the forage harvest, tracks remained and the crop was damaged. One must also assume that deeper down in the soil, nutrients were dislocated.

With so little sunshine and little heat, the ample ground water supplies still did not permit a full benefit. To be sure, there was massive growth, especially for varieties that do not demand much heat, but the assimilation and thus the concentration in nutrients were greatly diminished. The weather delayed ripening. A phenological delay of 5 to 10 days persisted. The advantages deriving therefrom for kernel formation in grain are not likely to make up for the disadvantages resulting from the delayed harvest. Weeds and fungus were heavy (mildew, blight, rot). Heavy downpours compacted the grain, especially on amply fertilized lots. Proliferation and partly double growth too occurred there. On overly wet lots, potatoes reacted to air shortages by turning yellow. The second corn, not yet having formed a proper climate for its firmness, almost stagnated in growth during the first two 10-day periods.

Due to the rain, there was much interference with field work. Drying conditionswere extremely poor, practically preventing all hay production and even placing ensilage production in doubt (long waiting periods, losses in nutrients, growing in). For fighting potato rot, one had to spray fast (strong growth and rains). There was no need for irrigation. Reservoirs were drained. For the harvesting-threshing of winter barley there were only a few days in the third 10-day period when meteorological conditions were favorable. But even there, strong dew formation further cut down the working time. But for the summer catch crop cultivation, the conditions were very good.

Meteorological Projections for Farming in September 1980

Abiding by optimum seeding periods for winter crop remains crucial for its yields. As the grain harvest was delayed this year, the straw must quickly be gathered. For improving soil structure and fighting weeds, we recommend, quite generally, intensive stubble working. That would, at once, also have advantages for the seed bed quality, for preserving the subsoil's water reserves, and for reducing the traction requirements in the seed or fall furrow. Since there has been so much rot in the potato plots, extensive and timely herbicide measures are recommended. Since the weeds are so abundant, chemical and mechanical measures should be combined. We must expect large-tubered and very wet crops that can easily be damaged. Thus great caution is called for in digging, processing and storing the crop.

DIFFICULTIES, PROBLEMS OF NATIONAL ECONOMY EXAMINED

Budapest VALOSAG in Hungarian No 5, May 80 pp 13-21

[Article by Janos Kornai, scientific adviser, MTA Institute of Economic Sciences: "Efficiency and Socialist Morality--a Few Dilemmas of the Hungarian Economy"]

[Text] Two Different Value Systems

The 1968 economic management reform brought tangible results.[1] Production has dramatically increased in the first decade since the reform. There is total employment. Since labor resources have become depleted, the production increase reflects mainly an increase in efficiency.

Although it would be worthwhile to analyze in more detail the achievements of the reform, I would like now to deal instead with a few difficulties and problems of the Hungarian economy. The Hungarian economist is in a special position for he is able to observe a great--and historically unique--experiment. I feel it is our duty to report the experiences of this experiment--not only the spectacular achievements, which can be followed even in the daily press, but also the less apparent concerns.

One of the objectives of the reform was to make the Hungarian economy more efficient. I will list below a few necessary conditions for economic efficiency.[2] I am not aiming at completeness; undoubtedly, there are several other important conditions that are missing. Also, I am not willing to reduce the conditions of efficiency to a small number of final conditions, that is, to deal with the question in an axiomatic form. I know only five conditions which were often mentioned in the debates on the Hungarian reform.

1. There is a need for a system of material and moral incentives that encourages the economy's participants--both the leaders and the workers--to perform better.

2. Thorough calculations must be made which take both profits and expenses into account. Our limited resources must be used economically. Inefficient productive activity must be stopped.

3. We must adapt rapidly and flexibly to the existing situation and external circumstances.

4. We need the enterprise of those who make the decisions: we need their initiative and willingness to introduce reforms and to take risks.

5. Every administrator and every decisionmaker must be held personally responsible for his or her work.

The five conditions above do not have any characteristically "socialist" content. On the other hand, they cannot be considered "capitalist" either. They are the general principles of efficient management. The official economic views of the East European socialist countries have always--not only since the reforms, but earlier as well--identified themselves with these requirements as the necessary conditions for the development of the economy and increased work efficiency.

Let us turn to another group of values which we will call in summation: the ethical principles of socialist management. Again, I am not aiming at completeness. There is a whole line of principles which were not included in the list. Just as before, when we talked about efficiency, I do not seek to formulate axiomatically and to arrive at a few final ethical postulates. I will be satisfied to deal with four principles. They may even partially overlap one another. At any rate, their position in the foreground is justified by the fact that they play an important practical role in the economy. All four principles appeared as early as the beginning of the labor movement, and within the capitalist system, but were redefined later when socialist economy was established. My article refers exclusively to the definition that is accepted in Hungary today.

A. The well-known principle of socialist waging is: "to everyone according to his performance."[3] This includes, among other things, the other well-known principle of distribution: "equal wages for equal work." Although the latter was originally formulated to help women, ethnic minorities and other disadvantaged groups get equal wages, its definition has been expanded in the socialist economy. It is evident that distribution according to performance should go hand-in-hand with the equal waging of the same work.

B. The principle of solidarity. Socialism abolishes the cruelness of capitalist competition which weeds out the weaker. The weaker must not be punished for his weakness. On the contrary, he must be helped to rise.

C. The principle of security: every member of the society should feel secure. This principle is closely connected with principle B above. Some of its more important implications are: the individual or a smaller community can feel secure in the knowledge that the larger community will come to help him in case of trouble. Society guarantees total employment--not just at the present, but once and for all. The fear of unemployment is a thing of the past. This can be said not only of total employment, but also,

in a more general form, of every achievement. The sense of security is strengthened by the fact that a standard once reached will be guaranteed by society in the future as well.

D. General interest comes before partial interest--regardless of whether the latter concerns the individual or a smaller community. This principle includes the priority of long-range interests concerning many generations over short-range interests, benefiting only the present generation.

The view has been established among economists of socialist principles that there is no contradiction between the two value systems, namely, that of efficiency and socialist ethical values. Perhaps it was Oscar Lange, the great Polish economist, who had the most illustrative formulation of this thought in his classic study of the theory of socialism, written in the 1930's.[4] Lange demonstrates a decentralized market economy, after Walras' concept, which is efficient and at the same time fits nicely into a social system built on socialist principles.

Experience does not corroborate this traditional view. It seems that clashes cannot be avoided between the conditions of efficiency 1 to 5 on the one hand, and the ethical principles A to D of socialist management on the other. The numerous dilemmas of decision in a socialist economy are created precisely by clashes of these two different value systems.[5]

Let me make a personal note here. Although I am striving to be as objective as possible in the analysis of the Hungarian economy's problems, my subjective view will emerge nonetheless. I am, on the one hand, an economist. And my other work involves mathematical economy. No wonder if my thinking has been "spoiled" by principles such as "rationality," "efficiency," and theories on the favorable effects of the decentralized market. On the other hand, my thinking has been deeply influenced by socialist social and ethical ideals. Thus, I also experience the dilemmas which every economist must face in the given characteristics of the Hungarian economy.

We will examine three problem areas, namely, incentives connected to profits, the survival of the enterprise, and, finally, the growth of the enterprise. In these three areas, the conflicts between the two value systems--the efficiency requirements and the socialist ethical principles--are especially apparent.

Let me begin by saying that this study will not delve into casual analysis. It would be a mistake to believe that the intention to enforce the ethical principles will violate the efficiency requirements, or vice versa. The actions of institutions or of decisionmaking individuals will be somewhat influenced, of course, by ethical considerations. But the roots of society's regularities of fundamental economic activity go much deeper. The topic of this article is thus much more limited. The article does not come up with any explanatory theory, but only attempts to analyze the theoretical possibility of bringing the two different value systems into harmony with one another.

Incentive Connected with Profit

One of the most characteristic endeavors of the Hungarian reform was to boost material interest connected with enterprise profits. This would serve the implementation of all five conditions of efficiency, especially the first two. (As a reminder: condition no 1 is to develop the system of incentives, and no 2 is thorough calculation and a strict balancing of incomes and expenditures.)

According to experience, however, interest in profits clashes with ethical principle A according to which everyone should have a share of the material goods "according to his performance" and receive "equal wages for equal work."

The Hungarian enterprises introduced profitsharing. This alone is a violation of principle A. The total income of two workers whose performance and wages are the same may be different if one has a larger share in profits than the other. In addition, the Hungarian enterprises acquired more autonomy in determining wages. A more profitable enterprise can pay not only higher shares of profits, but also higher wages, than a less profitable one. Because of all this, the income of workers with identical performance may differ widely.

Let us look at an example. Enterprise G is more profitable than enterprise H. It is possible that this reflects a better performance of enterprise G's management and workers. There is a better work discipline, more attention is paid to the quality of the products, and there is more flexibility in adapting to the circumstances. These might be the reasons for the higher profits. On the other hand, it is possible that they cannot take the credit for the increase in profits. There may be various factors at play that are outside of their control. For example, enterprise G inherited a better machine inventory from the period before profit-sharing than the less lucky enterprise H. Or the producer prices of both enterprises' products are centrally fixed and it just happens that enterprise G's prices have a high profit margin, and enterprise H's prices have a low one. Or both are exporting, and world market prices had benefited enterprise G, but not enterprise H.

The enterprise's management and workers consider the new income ranges "unjust." It is not they who are responsible for a small profit, or no profit at all. So why should they be the ones to be punished? They thus try to put pressure on the high authorities to level off the differences in incomes. And the higher organs themselves often feel that it is not right to allow excessively extreme differences, because that would contradict the egalitarian traditions of the socialist movement and the accepted principle of "equal wages for equal work."

There are many ways for the tendency of levelling-off to manifest itself. There are, on the one hand, general measures which prescribe how the

enterprise's gross profits must be divided between central and local taxes and other payments, the enterprise's investment and welfare funds, and the funds for profit-sharing and wage increases. Led by various considerations--among others, the intention to level off incomes--they prescribe quite complex formulas. This makes it more difficult to gain an overview of the system of interest, and this in itself decreases the incentive effect. But this is not enough. There are frequent ad hoc interferences with the finances of the enterprises to cream off "excessive" profits and to compensate for losses arising from "objective difficulties." In the final analysis, almost two-thirds of the enterprises' gross profits was taken away and redistributed in past years.

The often unforeseeable and incalculable redistribution, going through a hundred different channels, makes interest in profits illusory from many aspects. In microeconomy, the enterprise with high profits is suppose to limit its expenditures by the so-called budget limit. But under the circumstances mentioned above, the enterprise budget limit "softens up," that is, it does not really limit enterprise decisions.[6] The budget may be exceeded without any serious consequences. If the enterprise has financial losses because of uncovered expenses, the state will, sooner or later, pay them.

If an enterprise is in a difficult situation--because of outside factors that are beyond its control, for instance--it can react in two ways. One is that it can try to cope with the difficulties. The effort may be unsuccessful and the enterprise may go under. And even if the effort were successful, it would require sacrifices and self-denial. As long as the problems are not solved and the losses are not eliminated, the incomes remain lower than those at more fortunate enterprises. This way's objective is to adapt to the situation as flexibly as possible. The other way is to seek help from the high authorities: to send deputations, to complain and "to cry." "Lobbying" begins: the enterprise tries to find benefactors in the political and social organizations and high state offices who would use their influence on the enterprise's behalf. They would also use their personal connections. The second way's objective is to get financial assistance: as much state subsidy, tax relief, and "soft" credit as possible, and as soon as possible.

As a consequence of the second way, the enterprise, which acquired through the reform a greater autonomy to make short-range plans, almost voluntarily accepts tutelage. By seeking help, it continues or even increases its dependence on financial organs, banks and price authorities--in other words, on those central institutions which have an effect on its financial situation.

I would mention here the effect of the tendency to level-off the incomes based on undertakings involving risk, which is condition no 4 of efficiency.

Reform--be it the introduction of a new product, technology or organization or the exploration of a new market--entails risks. The unsuccessful are going to lose. It is worth the try, then, when success brings high profits.

In post-reform Hungary, the economic manager cannot lose, but he cannot win much either. There is no possibility for a "great advance." The conspicuously and exceptionally profitable enterprise will sooner or later be "tapped." The levelling-off of incomes more or less goes together with a levelling-off of performances as well.

These are, then, the first examples for the conflicts between conditions of efficiency and the ethical principles of socialist economy. The more the budget--and thus both the managers' and the workers' pay--reflects actual profits, the more it may be separated from waging principles that are based exclusively on individual performance and the more it becomes possible to "unjustly" differentiate between incomes. And, the other way around: the more consistently the principle of "equal wages for the equal work" is applied, the more the incentive effect of profit-interest will weaken.

The Survival of the Enterprise

The earlier topics are closely connected with the next topic of our analysis, namely, the survival of the enterprise. We have said in condition no 2 of efficiency that if the comparison of expenses with incomes indicates that a certain activity is inefficient, then that activity must be stopped. If an enterprise is much in the red for a long time, then it must be abolished in the interest of the economy as a whole, even if this means a big loss of prestige for the enterprise's management and a temporary lack of employment for its workers.

This requirement may contradict ethical principles B and C. The principle of solidarity means that the weaker community must not be allowed to fall. On the contrary, it must be helped so that it can continue with its activity and stand up. And the principle of security proclaims that no member of society should be afraid of falling and being set-back. He should be confident that his individual achievements--the possibility of uninterrupted work and guaranteed employment--will continue to be guaranteed for him in the future as well, especially when--and here is where this subject is relevant to the topic of the previous chapter--his problems are not caused by himself, but by external circumstances that were perhaps unrelated to him.

In the Hungarian economy, enterprises almost never went bankrupt--and ailing enterprises were never entirely liquidated--in the first decade that followed the reform. Not only the possibility of employment in general, but the actual job held previously, is guaranteed equally for everyone. After the world market price explosion, which caused tens of thousands of companies around the world to perish, not one single Hungarian enterprise went under. To use an extensively used term, the state treasury "shouldered" the losses. The "natural selection," resulting from economic competition, did not take place: the strong and the weak, the active and the passive, the initiator and the impotent, they all survived the storm.

There are many ways the state can assist enterprises that are in trouble. It gives special grants; in case of a product that has a fixed price, it allows a special price increase, it reduces the enterprise's taxes or tariffs, or the bank gives easier credit or allows the postponement of repayment, and so on.

There is no way to unequivocally evaluate the situation thus arising. Solidarity and security are in themselves a big asset in a man's life. The life of the enterprise--and its workers--becomes more relaxed, for the fear of life-and-death struggle has been eliminated. But this will in most cases induce leisurely and torpid behavior. If the survival of the enterprise is automatically guaranteed, then the management's individual responsibility will also be weakened--and the fourth condition of efficiency will be violated.

The guarantee of individual employment is a related problem and thus I will mention it here. The Hungarian economic system freed the workers from the fear of unemployment, which not only causes great losses for both society and the individual, but also humiliates human dignity and makes the worker cringe before employers. The abolition of unemployment is a historic achievement. We must face the fact, however, that guaranteed total employment--and its outgrowth, a chronic labor shortage--also has its dark side. People are not the same: there are conscientious and less conscientious, hard-working and lazy, thorough and superficial people. The fact that the labor market is a "sellers' market" puts both kinds of people in a favorable position. The chief of a shop or plant will think twice before firing a careless worker, because he might not find anyone to replace him. And if he does indeed fire him the fired person will not find this a punitive measure for he will in most cases easily find another job.

Both of these closely related phenomena--the guaranteed survival of the enterprise and the guarantee of individual employment or total employment--lead to very difficult and deep problems. Is a society capable of achieving high efficiency exclusively through positive financial and moral incentives and rewards for efficient work? Is a negative economic incentive--the effect of a fear of collapse and of individual financial and moral losses--dispensable? I myself am not sure what the answer is.

But this much seems to be sure, however. We are facing, here too, great dilemmas and conflicts between various value systems.

There is a contradiction between the requirements of efficiency, on the one hand, and the ethical principles of solidarity and security on the other.

The Growth of the Enterprise

Our next topic is the growth of the enterprise and, in this connection, the allocation of investments. The manifestations of the clash between the various efficiency requirements and the ethical principles are perhaps even more complex here than in the two previous areas.

Let us begin with a hypothetical system in which investment decisions are totally decentralized. This system would, no doubt, have some advantages with regard to efficiency. Conditions 3, 4 and 5 would be implemented more and more: risk, initiative and readiness for reforms would increase. Individual responsibility for investment decisions would become more flexible.

However--putting the ethical aspect aside for the time being--total decentralization would be in conflict also with some of the conditions of efficiency, first of all with condition no 2 which refers to the calculations of profits and expenses--when these categories are broadly defined. We would be facing the well-known problem of the welfare economy, namely, that the totally decentralized market does not, in the absence of any state or social interference, reckon with the external effects of local decisions that are not reflected in the market prices, including both the external profits and external expenses. This consideration leads us to ethical principle D, i.e., to the priority of social interest. If every enterprise makes investment decisions exclusively on the basis of its own interests in profits, then the danger exists that actions, which have primarily an external effect, will be pushed to the background.

Seeing this dilemma, the 1968 Hungarian reform set the objective of sharing investment decisions between the upper and lower levels of management. The reform laid down a significant decentralization when compared with the pre-reform period, but left considerable power, nonetheless, in the hands of the central institutions. Thus, for instance, almost half of the national economy's total investment was allocated in 1976 on the basis of central decisions. A little over a half of that is considered "enterprise investment," for it is the enterprise that announces the investment decision. But only half of the so-called enterprise investments are financed exclusively with the enterprise's own savings, in other words, about one-fourth of the total investments may be considered totally decentralized. For the other fourth, the enterprise must apply for state subsidy or long-term credit, that is, the central planning and financial organs, the bank and the enterprise will decide jointly.[7]

The new situation (the combination of centralization and decentralization) has many beneficial aspects. It makes it possible for the central organs to adequately balance the totally decentralized investments with centrally decided investments if the former's proportion is socially unfavorable. The allocation of the total investment may thus be adequately adapted to the central plans without making it necessary for the central office itself to divide all investment resources to the last penny.

The central office thus has the means by which it can guarantee the priority of society's interest over local and enterprise interests in case there is a conflict between them; it can serve the long-range interests of society (which are not always possible to express in terms of money) against the enterprise's short-range interests in profits. This combination of the power of decision makes it possible to use many different sources of

information to prepare individual concrete decisions. The enterprises supply the concrete and detailed information, and the higher authorities that take part in the decision supply the overall view of national economic relations and long-range plans.

The advantages are accompanied, however, by disadvantages. Since the majority of investments require central financial support or credit, decisions are preceded by lengthy bureaucratic processes. This diminishes the flexibility of adaptation. (Violation of the third condition of efficiency.)

The enterprises and lower-level authorities which have an interest in investments try to influence the higher organs. They try to present arguments, but they also use personal connections when they feel that this will promote an investment case initiated or supported by them. The economists and planners in the central organs are not impersonal representatives of the entire society's rationality; they are not philosophers of Plato's ideal state who embody a comprehensive wisdom of society. They are live people, living in the midst of society, connected by a thousand threads to their colleagues active in economic life. It is impossible to separate in their decisions the role of the strictly rational recommendations of economic calculations and personal intuitions that are subsequently "rationalized." Those who decide on investments in the higher organs should always pay special attention to the external effects of the actions that do not show up in the books of the enterprise concerned. However, this consideration is sometimes obscured by views reflecting the internal interests of the enterprise which recommends the investment action.

We must understand the sociology and sociopsychology of the decision process that precedes the investment in order to find an explanation of what happens if the investment is unsuccessful. It is simply impossible to determine who is responsible for the faulty decision. Since the decision was preceded by a multilevel, iterative informational and decision-preparing process, every organ and every person taking part in it is responsible. They are responsible--and yet they are not, for they can say that they did not want the investment this way, it was the negotiating partners who forced this compromise on them. In the final analysis, then, personal responsibility for investment decisions disappears. (Violation of the fifth condition of efficiency.)

Here we come to the explanation of the phenomenon mentioned earlier, namely, that the state gives a hand to the enterprise having serious losses in coming out of the trouble. It is not simply the "State" that helps but by virtue of using the state's money, all of those officials who--in the framework of the collective decision--took part themselves in the preparation of the action. Let us suppose that the losses were caused precisely by a faulty investment decision. Construction was delayed, the cost of buildings and machines were higher than expected, the new export product cannot be sold at the price hoped for, and so forth. Who pays for the bad deal? Everyone who took part in the preparation of the decision has an interest

in not letting the question of responsibility become critical. This in itself provides impetus to help the enterprise in trouble.

It must be added to the above that the situation in investment allocations is closely connected to the two problem areas discussed earlier. As I have mentioned, only a small proportion of the investments is implemented on the basis of self-financing or credit which is given by the bank exclusively on the basis of profitability. State subsidy or long-term credit may be given also to an enterprise which is in a bad financial situation. Thus the view has been established at the enterprise that its profitability is not closely connected with either its survival or even its growth. This is the main explanation for the phenomenon called the softening of the limits of enterprise budget. In the course of the investment action, the enterprise may, without any undue risk, overstep the financial resources at its disposal at the present or in the near future. The loss will, sooner or later, be covered by the state. This can, then, lead to irresponsible initiatives in investment actions and to squandering during implementation, both of which are detrimental to efficiency.

Let us summarize the above. On one side stands ethical principle D: social interest must have priority over partial interest. The implementation of this principle is not the only reason to limit the rights of the enterprise or local institution to decide on investment allocations, and social interest is represented by the extended authority of the central organs. However, the practical implementation of this principle clashes in many cases with the other side, namely, the conditions of efficiency. In addition to this, ethical principle D is not even implemented consistently: partial interest will prevail again and again, even when it is decisively contrary to society's common interest.

A Few Closing Remarks

We have outlined three problem areas that are connected with one another, namely, the questions of interest in profit and the survival and growth of the enterprise. We have seen how different conditions of efficiency and ethical principles can clash with one another. We wanted only to show the dilemmas which the Hungarian economy must face--not the solutions to these dilemmas. We especially did not want to do this so that the Hungarian experience would not be "advertised" as one that found a solution for eliminating all complex contradictions. Perhaps it is one of the most significant achievements of the past years' Hungarian practice that it does not want to create the illusion of completeness and settlement, but rather accepts the tasks of experimenting and pathfinding.

I do not wish to create the illusion either that I know the formulas to solve our problems. The "quack-economist" type is well-known. He is always ready to give advice and recommend a remedy for every economic illness. (Quite possibly, he recommends the same remedy for all illnesses...) Or another picture emerges, that of the "apostolic economist," with the

complete and detailed design of the ideal society, the realization of which he proclaims loudly and with self-confidence. I think I am far from these colleagues of mine. I belong to those who realize the limitedness of their science; we are still raising questions instead of giving answers. One or another comprehensive or more limited reform can only be recommended with caution. And even then, we must point out to those carrying out the reform that the change will entail both advantages and disadvantages, just like a medicine which has a healing power and, at the same time, an unwanted and sometimes extremely dangerous side effect.

There are no "clean" and perfectly "staunch" and "consistent" societies. Every real system is built on the practical compromise of contradictory principles and requirements. This is what characterizes the post-reform Hungarian situation as well. At best--and, fortunately, this is quite frequent in our country--the compromise is a "convex combination" of the benefits of the contradictory principles and requirements. At least in part, the beneficial effect of all principles that play a role in the given process will be apparent. At worst, however--and this is not infrequent either--there is no talk at all of "convexity." Two principles clash with one another where the total implementation of one to the exclusion of the other would entail both disadvantages and evident advantages. Their combination, however, accentuates the disadvantage of both and hides their advantages. Many times a kind of mixture of principles and requirements is created in which efficiency and ethics disappear simultaneously. Sometimes central intervention, as a repository of a decentralized market oriented toward efficiency and of socialist ethics, is a combination in which they mutually undermine each other's beneficial influence.

The reformers and the architects of economic institutions and mechanisms have a penchant for "perfectionism." In seeing the first weaknesses of the reform, they would like to reform the reform right away. For instance, more than 100 orders and statutory provisions have been created in the 11 years since 1968 to regulate enterprise profits and profit sharing. No matter how carefully thought out and smart some of them are, their effect is undermined precisely by their eternal improvement. The participants cannot really master the game if the rules of the game are constantly changed. Thus we reach a new dilemma here: the rigid institutional system, only partly suitable, stands in opposition to indecisiveness and the disadvantages of instability, caused by eternal improvement.

The traditions of economic science made us used to the view that everything can and must be "optimalized." It is thus understandable that the idea was born: an "optimal economic system," a set of the best "rules of the game," or the best regulatory mechanism must be designed. The person who strives to achieve this somehow thinks that he can visit a big supermarket where the various elements of the mechanism and the manifestations of the various beneficial attributes of the systems will be found on the shelves. On one shelf, there will be total employment as it has been realized in East Europe. On another, the high-level plant organization and discipline

as known in West Germany or Switzerland. The third shelf will display economic growth without recession; the fourth, price stability; the fifth, the fast adaptation of domestic production to the demands of the foreign market. The system designer has nothing else to do than to push the shopping cart in front of him, to collect these "optimal elements," then to go home and make an "optimal system" out of them.

This is, however, a naive pipedream. History does not maintain such a supermarket in which we can select what we want. Each real economic system makes up an organic whole. It may contain good and bad simultaneously, and in more or less set proportions. Anyone who wishes to take a stand in whatever system he would prefer can choose only from various prepackaged combination goods. There is no way to select from the various packages the elements we like and to leave there the ones we reject.

For me, it seems that it is impossible to create a closed and consistent socioeconomic normative theory which would implement without any contradiction a political and ethical value system and would, at the same time, guarantee management efficiency. It is impossible if it seeks to be realistic and wants to take into account the real nature of people, communities, organizations and social groups.

It is a more important and timelier task to study the existing societies and to explain the regularities of their operation. Our science must make it clear what compromises between the various normative principles the social forces create in the various social systems. We must strive to contribute to the goal of making the compromises' and contradictions' form of movement as sensible and beneficial as possible. This is a scientific activity which may yield social profits.

FOOTNOTES

This is the Hungarian text of the author's lecture in English, given in the Irish Economic and Social Research Institute of Dublin in honor of R.C. Geary, economist and statistician.

1. There is an extensive literature on the Hungarian reform. The following are of prime interest: Nyers (14), Friss (ed.)(5), Gado (ed.)(6), Gado (7) and Csikos-Nagy (3).

2. Economic science does not have an unequivocal definition of "efficiency." It is unnecessary here to get involved in the debate regarding the exact definition of this concept. It is sufficient if the reader clearly senses the association of ideas connected with the concept: efficient activity is the name of an activity which is done on the basis of useful results and the sacrifices made to achieve these results; an activity which makes a good use of the resources.

3. The classic definition of the principle was given by Marx (13) in his critique of the program of Gotha.

4. Vid. Lange, "On the Economic Theory of Socialism" (12).

5. The problems of harmony and contradictions between economic interests, productivity and the ethical requirements were discussed in numerous studies in the debates on the mechanism's reform, among others, the articles of Andras Hegedus (8), Tibor Huszar (9) and T. Ivan Berend (2).

6. On the softening of the budget limit and its effect on enterprise behavior, vid. the author's "Deficit" (11), to be published in the near future, and his article (10).

7. On the new spheres of authority in making decisions in investment allocations after the Hungarian reform, vid. Deak's study (4).

8. The problem area brought up in my lecture has a certain relationship with the questions of Arrow's famous "thesis of impossibility." Vid. Arrow (1).

   Two of Arrow's postulates define requirements of "rationality," and two other postulates define "political and ethical" requirements. The overlapping between Arrow's four postulates and the 5+4 requirements listed by me is, however, only partial. Arrow proves with perfect logic the impossibility of total reconciliation of his four postulates. I am attempting much less: I only illustrate with vivid examples the unavoidable conflicts between the two groups of values. According to my intuition, we could go further than that. A strict and axiomatic analysis of the contradiction, which I only mentioned, would also be possible.

ESTABLISHMENT OF NEW FOREIGN TRADE ENTERPRISE DESCRIBED

Budapest MAGYAR HIREK in Hungarian 18 Jul 80 p 7

[Report by Istvan Matko: "The First Swallow: Why the Generalimpex Is Established--the Advantages of Competition"]

[Text] At a recent ministerial conference at the Ministry of Foreign Trade, a resolution was passed on the establishment of Generalimpex, a foreign trade enterprise.

This is actually an everyday news report: one of our big telecommunications factories is being separated from the foreign trade firm with which it worked for 20 years, doing so in order to sell its products with the aid of another concern. The background is full of suspense, however, and what is more, it contains a strange fact: Orion is going to be connected with a new foreign trade enterprise which was created from Universal Ltd--a sales enterprise--which will now function under the name of Generalimpex.

But before describing its establishment or the reasons for its creation, let us dwell on Orion's decision.

Orion's Views

"Why did Orion need to change its partner?" I asked Bela Band, director of trade.

"Earlier, we worked exclusively with Elektroimpex, that is, more precisely, we are still working with it today, because only a decision for the change was made. Our television sets and other appliances have been exported by Electroimpex for the last 20 years in the most traditional way, on a commission basis. This no longer meets present requirements, and we had to look for other ways to meet the demands of the foreign market more flexibly and more efficiently; in other words, to meet the demands created by the competition. We were glad to hear about the change in Universal Ltd. This was an opportunity to establish producer--foreign trade relations most suitable for the demands of the market, that is, to do everything jointly: market research, exploration and marketing, to make joint decisions on products and markets to be considered, and to have the producer and the foreign trade experts take care jointly of the foreign marketing of the Orion brand."

"This sounds very nice in such general terms. But what is the guarantee that all of this will be realized in this way?"

"To begin with, we sign a contract with Generalimpex--a so-called pool contract--in which we agree on our joint activity. It is in the interest of both parties to abide by the contract."

"Why don't you wish to export by yourself? This would seem to be simpler and more practical..."

"Only on the surface. Our enterprise is not ready for the establishment of an independent marketing department. Also, it would do no good to use our internal resources for this, to create a new organization when the conditions for it do not exist. Practicality and sensible business interests dictate cooperation with a foreign trade enterprise that works flexibly. First, we want to use Generalimpex to export our television sets, and we will see what the outcome will be. We have thoroughly examined the possibilities for independent exporting rights and, in considering the pros and cons, we decided to take this step."

Reckoning With Small and Medium-Sized Plants

The expectations of the industrial enterprise, and even more the motives for its decision, suggest many things. It suggests, among other things, what concrete and practical possibilities exist for updating methods of foreign trade which are hotly debated by producers and foreign traders. Let us now take a closer look at the enterprise which is openly viewed by Orion with great expectations.

"What, precisely will be the activity of Generalimpex?"

"Actually, it will include everything," says Laszlo Darvas, director, while he arranges on his desk the pile of orders and letters of interested parties recommending programs. "Look at this one, for example," he points at one, "in which the cooperative of Vecses, well-known for its pickled products, is asking us to export its sauerkraut. The other one wants to export apple sauce and would like us to find possible customers. This one is perhaps the most interesting: the municipal management enterprise of Gyor wants to sell its turf abroad."

"How are Orion's TV sets related to this? What will the profile of the enterprise actually be?"

"Its name also indicates that we trade everything. The objective was to create a lively small enterprise which, primarily through its exceptional flexibility, would help to find a customer for every Hungarian product that is trying to find its way abroad. I have been toying with the idea of establishing such an enterprise for 2 years because there is a great demand for it. The situation is ripe now: the small foreign trade firm, employing less than 100 people, was created from our sales enterprises."

"If I understand it right, Generalimpex will thus compete with several small and large foreign trade enterprises which have been around for a long time. Do you get enough orders?"

"I think so. The preliminary surveys also supported our expectations. We have to take care of many so-called "small deals" in which we are especially efficient. I think, with this we can even fill the gaps... Incidentally, I must note that we are not afraid of competition either. We believe that orders should be given to the foreign trade enterprise which offers the best deals and which can work less expensively and with greater profit."

"This work needs well-trained experts and adequate interest."

"The team is fresh, it was put together recently, and it will obviously expand. For, as it is formulated in our deed of foundation, we want to be the foreign trade enterprise primarily of small and medium-sized enterprises and cooperatives, and thus we must not grow to mammoth size either. As far as the conditions are concerned, the interest of business dealers and experts was determined in a new way, according to the demand of the work, i.e., incomes will depend on the business deals and on efficiency. It is possible to imagine that someone will get, according to his interest in results, 30 percent of his fixed basic wage as a bonus. But it is even more important for our enterprise to emphasize relations with its customers. The enterprise can be efficient only if our customers are integrated into the foreign trade organization; this is the way we mix the expertise of both trade and production. The joint work and this broad definition of cooperation will definitely help us do a little better professionally than would be possible in the traditional way."

On the Road to Revival

As is known, foreign trade has also been affected by the new regulatory system since January 1980, its system of financial conditions having been fundamentally changed. The first experiences are favorable. It is certain that the "tax collector" character of the foreign trade enterprises has been eliminated. However, the new regulations were not responsible alone for the "new winds"; several updating and developmental conceptions will be realized which are supposed to improve foreign trade. The portfolio's agenda includes the study of the enterprise proposals of possible exporting rights as well as updating the foreign trade organization. The new firm to be established is an interesting and new germination among these. It shows that the foreign trade organization is on the path of its own revival--as exemplified, for instance, by the fact that it gives special consideration to small and medium-sized enterprises.

It is also worth mentioning cautiously that, behold, foreign trade can accommodate modest competition--or at least a competitive situation. For this small enterprise sometimes invades the territory of even those enterprises which had a monopoly up to now. Hopefully, the new Generalimpex will not remain the only "first swallow" in the profession.

ROLE, FUTURE OF AGROINDUSTRIAL ASSOCIATIONS WEIGHED

Budapest PARTELET in Hungarian No 8, 80, pp 30-35

[Article by Dr Gabor Soos, state secretary for Ministry of Agriculture and Food Industry: "The Role of Agroindustrial Associations"]

[Text] Since the development of the socialist large-farm system in agriculture, the producer cooperatives, state farms, food industry enterprises, and more recently forestry farms have been constantly striving to exploit the advantages of cooperation. In the course of this endeavor, the most varied forms developed, from the simple contractual system to economic associations of varying states of development.

In the middle of the 1970's a group of large farms in Hajdu megye initiated the development of an agroindustrial association on the basis of favorable results in domestic economic cooperation and the experiences of the socialist countries. Following a broad-scale analysis, the Political Committee shaped the basic principles for the organization and operation of agroindustrial associations, and then the government regulated in detail the organizational and managing order of operation.

The state decisions conceived as follows the goals of the new economic cooperation forms: "It is the goal of the agroindustrial association to coordinate more closely the economic activities and development plans of the participating state managing organizations and the agricultural producer cooperatives. With this they should contribute, to an extent exceeding the dimensions of their farms, to accelerating the development of production relations and to increasing the efficiency of management through a more comprehensive organization of production, processing and marketing. It is, moreover, the task of the association organization to promote an improvement in the living conditions of the producer cooperative members, employees and enterprise workers, their occupation, political and cultural development."

The agroindustrial associations represented a new form in the system of economic associations. Since we had not had experience with this form, it seemed reasonable to set up only several such associations in order to acquire our experience. Accordingly, the Council of Ministers set up the rules for licensing the development and the procedure of state supervision.

Up to now four agroindustrial associations have been formed. In 1976, the large farms of Hajdu megye which took the initiative were licensed to set up the Hajudusag Agroindustrial Association. Then in 1977, the Szigetkoz, Bekescaba and environs, and the Kalocsa environs agroindustrial associations were established. Forty-five producer cooperatives, 5 state farms, 12 processing or sales enterprises, and 3 associations joined the 4 agroindustrial associations. The area covered 260,000 agricultural hectares, with 46,000 workers.

Development of the Conditions

The operation of the agroindustrial associations extends back only 3 to 4 years. This period is characterized primarily by the search for and development of serviceable methods for organization and management, and thus--despite the results already attained--it is not possible to arrive at final deductions. It can be stated that political positions and state measures on the agroindustrial associations have turned out to be correct, there is no need to make basic changes, but on the basis of practical experience there is justification for further development of the management rules and the strengthening of material incentive.

The agroindustrial association operates as a legal person. Its highest leading organ is the council, whose members are the representatives of the participants. The managing organizations participating in the association keep their enterprise independence, and their legal entity.

The democratism of the leadership is being realized in increasingly broader scale. Association councils have been formed, and in basic questions--property contribution, development plans, the use of material means and funds, the balance, etc.--they are the decisionmakers. The working method of these councils is characterized by broad-scale discussions of the problems, and in making of decisions the realization of a simple majority on the basis of "one member, one vote."

The associations have developed their order of internal control and have set up the control committees. Experience shows that the control activities are well planned and suitable to the goal; their findings and recommendations guard the common property appropriately and help in the development of management.

The system of special committees for helping the work of the associations and giving a professional basis to the decisions has been successful. The members of these committees are the best experts from the member enterprises. They help establish the foundation of development plans with professional opinions and recommendations. They strengthen the common work and promote the development of a unified outlook.

The organization of the independent apparatus of agroindustrial associations, their working method and manpower have developed according to basic principles.

It is the task of the administration and its leader--the director--to prepare decisions, organize their realization, establish the objective conditions, and supervise the execution. The administrative bodies, consist of 9 to 25 persons, the number being appropriate to the task. The members are well trained in theory, and are experts in practical experience.

In the sense of the government's resolution, the agroindustrial association creates common property from the starting property provided by the participating organizations, from the transmitted funds, the amortization of common fixed assets, credits available for common developments, and state support. To pay its debts, it uses first of all its common property. In case of a deficit, the participating managing organizations are guarantors of the association's debts in proportion to their property contribution.

The agroindustrial associations have established their material bases appropriately, At all four associations, the starting property and the paid-in property contributions assured an adequate source to begin managing. The property contribution of the farms consists of their full activity, whereas the food industry and commercial enterprises make their contribution in proportion to the value of the goods they receive from the participating farms. In the past 3 years, the farms of the four associations have given almost 446 million forints as development contributions, almost 10 times as much as their 46 million forints in founding property. The food industry and commercial enterprises contributed 139 million forints in property, about five times their founding property of 29 million forints. On the basis of the experience, the further development of the contributions is justified in such a way that instead of the realtively rigid annual contributions, the development programs of the associations should be better adjusted to the material possibilities of the participating managing organizations.

In the framework of the associations following their formation, a broad-scale economic activity has developed. In comparison with other forms of economic association, their activities are more proliferating and embrace the entire production organization and managing area of the participating managing organs.

For the development of production and more favorable area distribution, they worked out a branch development program based on the use of propagation plants and technology, and worked on their realization in an organized way. The initial results of this process, which will last a number of years, are encouraging. In accordance with area features, at the Bekescsaba association the areas for oleaginous plants and corn were rearranged; in the cattle branch at the Szigetkoz association, dairy and meat production were divided by specialization on four farms each; the Hajdusag association located its sugar beet production immediately in the area of a newly built sugar mill; important specialization work was also carried out in the vegetable production and livestock breeding branches.

Economic Activity

The associations regularly analyze by branches the development of natural indexes and costs of production, the factors influencing these, and the

causes for the differences. They give help to their farms, which have the same resources, but varying results, in developing an efficient operational and leadership organization. They follow with constant attention the financial situation of the farms. the development of the managing conditions, prepare analyses based thereon, and on the basis of the evaluation made at council sessions they accept proposals for the improvement of management.

In recent years the agroindustrial associations have developed manifold, common services. Nine to 15 kinds of services are available, performed by various associations, to assist in the work of the member farms. Accelerated promotion in the preparation of investments is served by the establishment of planning divisions, which meet the planning requirements of the associations and the farms, and on the basis of experience thus far they do so very successfully. To implement investments more rapidly, they have established new construction industry capacities at the Szigetkoz association, and they have regrouped and coordinated the construction industry divisions at the Hajdusag association. Each association is developing a common agrochemical center and working to establish a standardized motor pool and improve it by specialization for combined parts supply. They have worked out common fodder management programs. Despite the results achieved in developing a common service activity, much care must be devoted to this area in the future.

The common planning, production organization and service activities have contributed significantly to an increase in the production of the farms participating in the associations, and to a reduction in existing differences in yields. On the average for the four associations between 1976 and 1979 the production value of total operations--calculated at current prices--increased by 33 percent, which exceeds by 5 percent the average growth rate of state farms for the same period. Average production on large farms in the association in the past year exceeded the national average for wheat by 780 kilograms, corn by 1,550 kilograms, and sugar beet by 5,240 kilograms. Differences among the member farms declined, primarily as a result of more rational fertilizer management, the use of better stocks, and more efficient technology. In poultry breeding, laying hens more than doubled, sheep stocks increased by 110 percent, and milk production per cow grew from 2,458 to 3,839 liters.

The four agroindustrial associations have devoted a great deal of attention to the realization of common investments. Up to now, 21 different kinds of investments have been finished with a total value of 800 million forints. As a result the four poultry breeding sites are producing annually 7,000 tons of broiler chickens, and the three potato storage bins assure storage and handling for 27,000 tons of potatoes. A new poultry incubator is operating as well as a sheep and cattle pen, a vegetable storage facility, a site for drying paprika, a sowing seed dresser, and so forth. Four other important investments are under implementation: livestock breeding and industrial facilities, and agrochemical sites. It has been our favorable experience that all investments are realized more rapidly than average, in an organized way, and with good quality results. The natural production indexes are good,

and cost development is also satisfactory. Processing industries participating in the associations receive from the common production and from their own immediate environment raw materials in large quantity and of uniformly good quality. The significant reduction in transportation costs and the quality improvement extend economic advantages within the association both to agriculture and the processing industry.

As a result of the operation of the associations, the vertical relations of agriculture and the food industry have improved. According to experience, this relation develops most vigorously in those associations or branches where the large farms of the associations supply the food industry plants in greater part or at least to a significant degree with raw materials. From this point of view the relationship may be judged good of the Kalocsa Seasoning Paprika and Canning Industry Enterprise, the Debrecen Poultry Dressing Enterprise, the Hajdusag Sugar Factory, the Bekescsaba Canning Factory and the refrigeration unit, and the Bekescsaba and Gyor Zoldert Enterprise.

In addition to the production relations, the development of personal relations between the agricultural and industrial operations participating in the association is worthy of note. The leaders and specialists of the member units have come to know one another's work and problems even in this short period of time. A higher level of common thinking is in a state of development and growing constantly stronger, something which has a favorable influence everywhere.

Party Guidance and Political Work

The area guidance of agroindustrial associations belongs to the megye party committees. With the organization of the agroindustrial associations, and during their operation, these party committees have given complex assistance to the practical realization of the established guidelines. Their forums have discussed the work experiences of the association belonging to their sphere of authority and have given useful guidance to the solution of further tasks.

Within a short time the megye party committees established a council of party secretaries in all the associations. To unite them, they entrusted one of the working members of the megye party committee. The consultative committee, including all the party secretaries of the member organizations, receives information from time to time on the upcoming association tasks, the situation of the body and the specialized leadership, the more important subjects to be discussed, plan coordination and development ideas, and on their social and political effects.

Experience thus far shows that the council of party secretaries is a body which assists, gives opinions and promotes the realization of resolutions in their economic units and which orients the basic institutions on an up-to-date basis. Thus, it appropriately shapes the views of the party members and

mobilizes them for the tasks. They hold regular meetings, in general every half year. According to practice as it has developed, they put the more important problems on the agenda: The annual and the five-year plans, the common investments, the current production results, the final annual summaries, the effect on the living and working conditions of the members and the employees, and the social influences of the new cooperation form. With their observations and proposals thay are positively helpful in the successful solution of the tasks of the agroindustrial associations.

At the initiative of the council of party secretaries, a Council of KISZ [Hungarian Communist Youth League] Secretaries was established in each of the associations. This significantly helps in forming the view of the young people, and their love for their trade, and it also strengthens the youth movement. At the praiseworthy initiative of the members from the Hajdusag, the HAGE [Agroindustrial Association of the Hajdusag] sport days were arranged in 1978; and at the same place in the summer of 1979, agroindustrial youth days were held at the initiative of the KISZ Central Committee. On this occasion they arranged lectures with discussions, exchanges of experience, and plant visits. This summer they are planning a similar program at Bekescsaba.

Semiannually, the Ministry of Agriculture and Food Industry holds a national conference of leaders of the agroindustrial associations. The megye party leaders and council leaders participate and they give appropriate orientation to the council of party secretaries and to the youth on the situation of the associations, broad-scale information on their common tasks for the formation of a common outlook and action.

Consistent party guidance and manifold political work will be indispensable in the future as well in order for the role of the agroindustrial associations to be realized adequately.

The Future Tasks

Agroindustrial associations--which do not enjoy the benefit of supports different from those in general--changed the production structure in a favorable direction within a relatively short time. Work distribution among the participating operations is developing appropriately, the production level is more even, and they were able to realize common investments well serving management development. All this shows that the basic concept of the agroindustrial association has proved successful, it has worthily helped in given places in concentrating intellectual and material resources, developing production, and making management more efficient. At the same time, it can be stated that the associations still do not adequately exploit their ecological features; they still do not coordinate in a planned way the development programs of the member enterprises with common activities; and there are still tasks regarding the procedure of property contributions, and the organization of vertical relations.

On this basis the Political Committee and the Council of Ministers, in recognition of the results, made the evaluation that the experiences thus far are still insufficient for final judgment of the economic association form, and do not as yet give an adequate basis for the organization of newer associations.

The major tasks in the development of agroindustrial associations may be summarized as follows:

--Even better exploitation of production conditions, natural features and material means;

--a more balanced development of the member farms and enterprises, development of a more efficient management;

--the working out and circulation of new, more economic and less material- and energy-intensive, less expensive technologies;

--rapid conclusion of common investments and putting these into operation;

--strengthening of the vertical relations among the raw-material producing and processing or marketing member enterprises;

--more effective use of intellectual and material resources and their concentration on the most important tasks serving development.

On the basis of experience there is also reason for examining certain provisions of the basic documents. These include membership relations, and resignation and acceptance of new members. There is also reason to analyze whether the area of operation by agroindustrial associations does not require a minor amplification from the viewpoint of strengthening their regional character.

We wish to inform public opinion more factually and broadly than before regarding the goals, results and problems of the associations.

Exploiting Advantages of Economic Associations

In addition to further developing the activities of the agroindustrial associations, it is justified for the agricultural, forestry and food industry operations to exploit more intensively in the future the possibilities latent in the various forms of economic associations. A basis for this is given by the fact that variegated forms of economic cooperation have developed among the operations, and in recent times we have acquired manifold experiences.

The most general of enterprise relations is the contractual system based on equal rights and mutual interest. To develop this further it is most important that contractual discipline be strengthened, as well as partnership relations enjoying mutual advantages, and the sharing of risks.

The system of cooperation between economic associations and the farms has been strengthened by the production systems which have developed on a broad scale over the past 10 years and have become the carriers for organization and circulation of industrial-type production in agriculture. At present, 73 production systems are operating, and about 90 percent of the farms are members of one of these systems. The production systems bring the biological, technological and technical-scientific factors of production into the framework of plant and work organization, and make production more and more economic.

The most differentiated forms of cooperation for production and service have developed among the farms in the framework of associations. Of the 800 associations operating in the whole area of the economy, approximately 700 represent the economic cooperation of agricultural, food industrial and forestry operations. The economic associations concern themselves with highly varied tasks and perform activities which an individual farm would find it difficult to organize by itself. Therefore, in addition to the farm-enterprise magnitudes that have developed, the managing organizations --realizing the principle of voluntarism and mutual interest--have used, in increasingly broader scale, the advantages latent in the various kinds of association. The economic association should not harm the independence of the cooperating enterprises, and democratism should be realized in leaders and in decisions.

All these cooperation forms and associations are important managing forms of our agrarian economy. Their purposeful organization and efficient operation helps, to a great extent, the successful realization of our economic tasks, and the carrying out of the party's agrarian policy.

PRIVATE PLOTS, FARMS NEED AID DESPITE ADDED BURDEN

Budapest PARTELET in Hungarian No 8, 80, pp 36-40

[Article by Gyula Poden: "Tasks in Development of Private Plots and Auxiliary Farms."]

[Text] A party and government resolution was passed in 1976 providing for the promotion and organization of this work. The Secretariat of the Central Committee recently reviewed the implementation of this resolution. On the basis of overall experiences it could establish that production inclination grew on private plots and auxiliary farms in response to manifold measures, the improving level of material and technical supply, and appropriate economic conditions.

Production on private plots and household farms in recent years has increased in accordance with the goals of the Fifth Five-Year Plan. The gross production value of this sector last year--at unchanged prices--was 61 billion forints, that is, 11 percent over that in 1976. As a consequence, the sector's share in gross agricultural production hardly changed. While the number of producers declined significantly, their production became at the same time more specialized, and particularly the number of those equipped for commodity production increased among the young.

Livestock breeding continues to be of definitive importance in their activity, making up as it does 63 percent of the total production of auxiliary farms. Within this, slaughter pig production is the most important: more than 50 percent of the pig stocks are in this sector, and in addition to self-supply, about one-half of the marketed fattening pigs come from this sector. Small farmers produce one-fifth of the slaughter cattle, one-third of the dressing poultry and rabbit meat, and the entire output of honey. On the capitalist markets these are marketable at good prices. Annually they bring more than $50 million in receipts to Hungary. There are also some problems in addition to the good results. We have not succeeded in permanently reducing the decline in cow stocks, and over a 7-year period about 100,000 small producers gave up cattle breeding. In some cases, fodder supply problems have also played a role.

The role of small producers in arable-land crop production has declined, but in the production of several special crops like poppyseed, dry beans, and potatoes they continue to be important. In response to demands, vegetable production has also developed dynamically. More than 1 million families are engaged in their production. It is particularly noteworthy that these farms have increased foil-covered production from 13 million square meters in 1976 to 40 million square-meters--which is 70 percent of the total foil-covered area.

In grape and fruit production the development has not been even. Grape planting areas declined by 25 percent, whereas garden and fruit areas increased one and one-half times. Unfavorable weather, the difficulties in obtaining propagation plants (sweet and sour cherries, nuts, etc.) are limiting production. Despite this, the role of the small producer continues to be of definitive importance in the production of plum, raspberry, strawberry, and peach.

The Condition System of Production

Small-farm production is based on family labor, and outside manpower is used only to a negligible extent. Its production continues to be characterized by fragmentary manpower which does not hinder the work of large farms, and does not develop at their cost. The number of active agricultural earners among small producers is declining, while at the same time the ratio of non-agricultural earners and pensioners is increasing. The judgment of this activity is very important both from the viewpoint of their further development and assistance.

From year to year, the biological base of private plots and auxiliary farms--sowing seeds, propagation materials, breeding animals and fattening primary materials--is available at a rising level. Sowing seed supplies for vegetable production are constantly improving. The feed-grain fodder supply is also constantly expanding. Fodder stores are operating at all settlements in the country. Fertilizer and herbicide consumption has increased. In the past year, there were 130,000 tons of fertilizer to meet demand. Herbicide purchases increased by 30 percent within 4 years. However, we were unable to meet demand for several fungus and insecticidal agents of capitalist origin. By far the greatest share of the chemicals in shortage can be replaced by domestically manufactured products or by imports from socialist countries.

Small machinery, as compared with the goods base in 1976, doubled, and the value exceeded 1 billion forints. The shortage in the quantity of agricultural implements has been ended, but the purchase of special or less expansive domestic tools is still difficult. The import products, on the other hand, are more expensive than the comparable domestic goods. In most of the traditional hand-driven small machinery and in livestock breeding equipment, the supply is adjusting to demand. An adequate supply of milking machines for small household farms became available only at the end of last year.

The increasing demand for small, internal combustion garden machinery has been met only partly because of the slow development of domestic manufacture and despite considerable capitalist imports--$4.6 million in 1979. The start of broader scale production of small tractors in domestic cooperation may bring a substantial improvement in the situation. There is a great need for this because, with the younger people who have joined in production and the urban population there is a strong effort at easing labor and modernizing agricultural small farming. It is only with such satisfaction of their demands that we can assure they will be permanently engaged in private-plot activity.

A continuing problem is the satisfaction of delivery demands, although the value of such services on the large farms and the afeszes [general consumer and marketing cooperatives] increased by 30 percent as compared with 1976. A general problem is that we have too few small-capacity delivery vehicles. The solution is primarily the task of the large farms that organize small production, but the situation could also be eased by privately licensed acquisitions of tractors, trailers and small trucks.

The development achieved in the past 4 years has been contributed to by the incentive effect of the economic regulatory system, as well as by the many-sided economic-political and production organizational measures. Owners of private plots and auxiliary farms may buy fertilizers and herbicides at the same--state subsidized--price that the large farms pay. For certain materials they receive preferential support: foil and foil frames, and for certain activities which are particularly important from the economic point of view, like cattle breeding and grape and other fruit production.

The tax system has become unified and easily reviewable, and this has been favorably received by the small producers. The number who pay taxes on receipts over 150,000 forints has increased fourfold within 3 years, but even so last year this meant only 1,638 persons, or 0.1 percent of the taxpayers.

In the development of production, loans play an important role. In the past 4 years a total of 526,000 small producers have taken out production loans of 4.8 billion forints from the National Savings Bank, or from the savings cooperatives. The extent of the average loan rose from 8,000 forints in 1976 to over 10,000 forints in the past year.

It is necessary for the small producers also to be aware of the economy's situation and of the change in energy prices. In response to the economic regulators in effect since 1 January 1980, certain cost elements will increase, and it is expected that these will stimulate the producers to economy. It serves the maintenance of material incentive and the inclination to produce that the rise in buying prices, all in all, counter the increase in costs. It is true that this does not mean an automatic counterbalancing in every area: where the cost increase is greater than average because of the character of the production--heated production under foil--or the

specific results are less, a transformation is necessary in such a case of the "product structure" to a more economic management. This must be promoted with circulation of information and expert advice for if the small producers do not adjust flexibly to the altered circumstances the profitability of their work will decline and it may happen that many will abandon production. In this area we must observe with particular attention, pig and poultry breeding and vegetable production under the cover of foil, which is high in energy demand.

It is a nationwide problem that frequently the large farms do not recover their costs relating to private-plot production. They generally reckon the materials and services as overhead. In addition, their preoccupation with the private-plot operation branches requires a great deal of time and energy, which is also a burden on the managers. This problem cannot be neglected because in 1978 the value of produce and animals marketed through common farms exceeded 15 billion forints. Now, because of their more difficult material situation, the large farms are trying to reduce their costs and increase their receipts. For this reason profitability may decrease for the small producers, which may cause stresses in production.

In recent years supplementary income has operated as an important incentive and driving force, and there were many who wanted to compensate in this area for the effect of the 1979-1980 consumer price change. Since the owners of private plots and auxiliary farms are doing this increasingly difficult and specialized production work in order to increase their income, their market or income sensitivity has grown. In this situation the strengthening of the organizational level based on mutual interests is of great importance.

With Greater Organization

The organization of production has constantly improved in recent years, and small producers find their security in relation with the large state farms and the afeszes. Nowadays the number of private plots and auxiliary farms organized by large farms is near a half million. For the independent organization of small production, the tsz's [agricultural producer cooperatives] established independent private-plot branches in which 2,900 specialists are working, including 1,560 who were released to help in this activity. The private-plot branch works on the basis of a separate accounting, organizes the activities of the small producers, gives advice, and cooperates in assuring the conditions of production, in marketing, etc.

In the past 4 years the afeszes increased the number of specialized groups to nearly 2,600, the manpower in which exceeds 200,000. Aside from a few exceptions, the specialized groups operate in the framework of the afeszes. The great majority of them are occupied with rabbit, pigeon, and pig breeding, with vegetable production and bee-keeping. Parallel with the rise in production, the afeszes strengthened their guiding and buying apparatuses

and increased the number of engineers and technicians. They have advanced a great deal in the material-technical supply of production, in broadening the specialized store network and in expanding the giving of expert advice.

The forms of relationship are wide in scope; from multiyear contracts through fattening of pigs on a contract basis and the joint buying of basic materials to the operation of specialized groups, every different kind of version can be found. But despite the development, producer confidence and security is not complete. The reason is, on one hand, that the buying enterprises have not as yet joined adequately in this integration and, on the other hand, that there are disputes and tensions because of the marketing cost distribution and bureaucratic organization. The state of organization is the highest in pork production and buying. Ninety-eight percent of the fattened pigs are bought by designated organizations. The remaining buying and food industry enterprises are still only at the initial step.

For the improvement of technical supplies, the setting up of about 70 machinery loan establishments proved to be a correct initiative. Also favorable is the fact that 380 large farms, as well as a number of afeszes, have begun the repair of small machinery and equipment.

The coordinated activity of the councils--to create harmony among the farms, afeszes and buying enterprises--was more lively at the beginning phase, and the effects of their measures were better felt in the broadening of production, establishing conditions, and handling nonproducer cooperative members with equal judgment. Their attention has dropped in recent times, they do not follow now with such critical eyes the whole process of production, and thus they do not notice the lesser or greater deficiencies and distortions that may appear from time to time.

The social organs--the Patriotic People's Front and the interest representational organs--also help in the development of a correct outlook. They cooperate in the organization of the work and in recognizing good results: every year they decorate about 1,000 persons, or award them plaques in recognition of their outstanding achievements.

Better Exploitation of Resources

In this year when the Fifth Five-Year Plan is being concluded and the Sixth Five-Year Plan is being prepared, a realistic accounting is taking place in every area to enable the targets for the future to be exactly defined. In designating agricultural tasks, a great deal of attention must also be devoted to the development of private-plot and auxiliary farm production development. The goal in this sector, too, is the increasing of production at a higher level. To this end, it is necessary to improve the guiding and organizing work, and assure the condition system for this purpose. This is no small task and requires the more consistent realization of the 1976 party and government resolution. For this reason, the party organs should continue to pay attention to see that the work starts or continues with an upswing

at every level and in every area. Existing errors should be corrected, and distortions eliminated. They should press forward with development production by taking into account the new requirements.

The work is made more difficult by the fact that modifications from time to time in the regulator system affect the activities of this sector as well. Here too we must press forward with more economic, efficient management. On small farms also the reserves of profitable management are to be found in the better use of local resources and possibilities.

While the party organizations are working on discovering the reserves, they must not forget to see to it that the producer meets his calculation, but not at the cost of the integrating operation. Everyone should realize a fair income because otherwise there will be damage to the individual, the large operation, and the national economy. Therefore, they should observe with care the entire process of production and buying so that they will be able to eliminate the tensions with speed and timeliness.

We need an economic regulator system which will stimulate private-plot production and establish incentive for the organizers as well. It is no less important that the material-technical conditions of production should continue to improve. In addition to the latter, it is necessary to devote care to intensifying the certainty of buying, particularly marketing. In the recent period there have been many weaknesses in this field in addition to the fine results. The work of flexible, well-functioning organizations helps small production, while disorganization sets it back.

It is necessary to develop an organization form which will assure a better state of organization. This means the small producers should receive timely information on the goals and production demands of the economy, and the organizers of production should be informed of the intentions of the small producers. We must take this into account also in preparing for the Sixth Five-Year Plan, but we cannot neglect it either in preparing the annual plans. We must not ruin respect for stable, multiyear contracts. In annual contracts, however, it is advisable to organize the producers flexibly and in accordance with demands, for example, in vegetable production in making contracts for vegetables that can be substituted for one another.

It is an indispensable condition that appropriate harmony should exist also among the integrators of production. In this the councils also have a role in addition to the large farms, and the buying and marketing organizations. As their part in guiding agriculture it is the task of the community councils to observe small production carefully, prorote it, and supervise the observance of orders.

The results achieved in private-plot and auxiliary farm production are important, but it must be developed further in the effort for the development of fully organized small production. It is also necessary that more and more people understand this, that they interpret the tasks uniformly, and that they help in private-plot production.

In agitation and propaganda work, the party organizations approach these problems from the aspect of helping and developing production. They should call attention to the fact that in addition to modern procedures, means and varieties, the traditional and inexpensive solutions should not be forgotten because in many instances their profitability is greater. This is in the collective interest of not only the small producers, but also the economy, because nowadays the utilization of byproducts and increased economy is a primary economic political task.

WHEAT GRADING SYSTEM, QUALITY OF HIGH-YIELD FOREIGN WHEAT EXPLAINED

Budapest MAGYAR NEMZET in Hungarian 10 Aug 80 p 7

[Report by Sandor Illes: "What Kind of Flour Is Used for This Year's Bread"]

[Text] The harvest is coming to an end; there is hardly any cereal still standing in Baranya, Csongrad and Bacs-Kiskun megyes, and work is progressing well in Pest, Bekes and Szolnok megyes; Tolna Megye reported that 80 percent of the crop had been harvested by the end of the week; Zala Megye also made up the arrears and harvesting is being done at full capacity in the other megyes as well. Harvesting in Nograd Megye is being made easier by the fact that the crop was not lodged.

The size of the crop cannot yet be estimated but experience shows that this was a good year as far as quantity is concerned. The ears are full, there are many grains. But what kind are these grains?

It is well-known that even wheat is being purchased this year according to quality. More is paid for better-quality wheat which has a higher gluten content. The better wheat will go to the mills and that is what the bread will be made from. Thus the bread will also be better.

Three Categories

In the old times, Hungarian wheat was famous for its quality, especially that which was grown alongside the Risza and at Bankut, the type improved by Rudolf Fleischmann, but even the later species. Older people still remember the articles in the papers which reported that the bakers of London put a sign in their windows that their pastry was made from Hungarian flour.

Today, however--let us face it--we often complain about the bad-quality, gluey bread. Did the bakers forget how to bake bread? It is not always they who are at fault. Often the quality of the flour is bad. Where is the legendary hard wheat of Bankut now?

Quality is worse, quantity is larger--this is how the present situation can be described. New species of wheat were domesticated in recent years. These species yield large crops and are suitable for combine harvesting. Only

they are not as suitable for bread. This is why it was necessary to take delivery of the crops according to quality in order to give better wheat to the mills.

We talked about this with Dr Jozsef Bagi, vice director general of the Grain Trust and nationally renowned expert in this area. He informs us that good-quality species of wheat were still being grown in Hungary in the 1950's. Essentially only two species were grown in those years.

"Undoubtedly, the inner quality of the wheats grown then was better than that of the present species," he says. "Generally, it met the quality requirements. For this reason, we usually examined the storage and milling characteristics of the wheat instead. Less attention was paid to the inner quality. At present we have larger crops and the quality of wheat has deteriorated accordingly."

About 20 species of wheat are grown on the farms in Hungary today. There are three categories of quality: Improving wheat, miller's wheat and fodder wheat. The improving wheat is eating wheat, having the highest gluten content; the second category is standard wheat and the third is the poorest, used only for animal feed.

Gluten That Is Good

"The new standard differentiates between these three kinds of wheat," continues the vice director general. "The improving wheat's raw gluten content is 35 percent. These wheats yield smaller crops. This category includes five species of wheat, some of which are new Hungarian species such as the MV-4 and MV-5, both from Martonvasar.

"The mass wheats yield 50-60 quintals but their gluten content is lower. Wheat with an ideal gluten content, such as the GK Tiszataj, does not yield more than 45-46 quintals. We have also domesticated some Yugoslav wheat, such as the Pertizanka or the Rana. But several areas have problems in growing these.

"Categories AI and AII are the most suitable for the baking industry, having the highest gluten content. Miller's wheat does not have as much gluten, it belongs to categories BI and BII. Quality wheat is used to improve these. That is what improving wheat is. With regard to the third category, the mass crop, it would be suitable only for baking flat cakes. Such is the Libelulla and many other Italian species. They yield a large crop but their quality is low."

The preparation of the new delivery system was preceded by a 2 year series of experiments: In 1978 and 1979 a thorough comparative examination was conducted at numerous delivery stations, and the best-quality species were determined on the basis of the experiments.

There are, of course, local characteristics as well which must be considered in the future. It happened that the gluten content of the high-quality GK Tiszataj was over 35 percent in the country's good wheat-growing regions but reached only 32 percent in Zalaegerszeg and the surrounding area. The gluten content of this specie varied between 21 and 43 percent. Of course, this percentage is affected by the weather, the time of harvesting and many other external factors.

One Hundred-Two Laboratories

"We are purchasing wheat this year at 2,000 delivery stations," continues Dr Bagi, vice director general. "Wheat quality control is done in 102 laboratories."

"What method do they use?"

"At delivery, the basis is generally the weight per hektoliter, this is the old measure. We also use an instrument called the Valoriograph. The 102 laboratories mentioned above use a mill and a bakery jointly. The wheat is milled with small stones, the flour is then kneaded, with salt, yeast and all other materials, and then leavened. The small baking oven then bakes the dough. This way we can also taste the quality of the bread. Is the flour good or unsuitable for baking bread?"

"What is the difference in the delivery price?"

"This year's official delivery price is 280 forints for each quintal of fodder wheat, 310 forints for miller's wheat and 325 forints for eating and improving wheat."

"And what will be the quality of this year's wheat? Can the bakeries make good bread from it?"

"The quality of this year's wheat varies. For the time being, the overall quality cannot yet be determined; this can be done only when all crops will be delivered. However, harvesting will last another 2 weeks or so. The experts say that the quality of this year's crop, because of the bad weather, is expected to be lower than required. On the other hand, there will be a larger crop of high-quality improving wheat. By mixing this with miller's wheat, it will become possible to make the flour used for baking bread more stable."

"Which means that the quality of the bread will improve?"

"Yes, it will, but to achieve this it is necessary to mix the flour and to introduce and employ processes that improve its quality. The conditions for this do exist and thus we can hope that the bakeries will be able to make better-tasting bread from this year's crop..."

DEPUTY MINISTER INTERVIEWED ON CLOTHING INDUSTRY PLANS

Budapest MAGYAR HIRLAP in Hungarian 17 Aug 80 p 5

[Interview with Imre Szabo, deputy minister of light industry, by Gyongyi Cseszak]

[Text] Light industry, including the textile clothing industry, has had many problems in recent years. The world market changes, the effects of the price explosion, over a broad area, have influenced profits and sales possibilities unfavorably. Primarily, structural change and modernization may help in these problems--and quite a number of programs have been prepared to this end.

Gyongyi Cseszak discussed with Imre Szabo, the deputy minister of light industry, how the textile clothing industry is preparing for the Sixth Five-Year Plan.

Imre Szabo was born in 1930 in Vasvar. He completed a technical university education. He has had various positions in the textile industry: in 1963 he became deputy department chief in the Ministry of Light Industry and subsequently department chief; in 1977 he was appointed deputy minister. His area of work is the textile clothing industry, as well as technical development and industrial policy.

[Question] It is our impression that within light industry it was the textile industry that made the best recovery from the shock caused by the slump. Despite this, many open problems are still waiting for solutions. What are those areas and enterprises where the Sixth Five-Year Plan must be started with inevitable changes?

[Answer] There is not a single clothing enterprise manager who is not bothered by the eternal question: am I manufacturing a good product at a good price and selling it in a good market. The government and party resolutions on the modernization of the product structure, as well as the stricter norms, require us to give equal importance to all three of these questions. But in medium-term planning it is still the development of the product structure that is the most important. And since all planning work

is built on the basis of the preceding period, I would like to say a word or two first about the Fifth Five-Year Plan.

The development of the clothing industry in the Fifth Five-Year Plan period can be divided into two phases. In the first 3 years we were still increasing quantity of production. In the past 2 years, we have restrained this process, and selection has been emphasized in order that we might prevent a greater worsening in the terms of trade and improve profitability. We sell domestically one-half of the products of the clothing industry, and one-half we export. Our products are bought by 80 different countries, and the world market influence can be sensed in both enterprise and industry management. In the first half of this year we overfulfilled our plans for exports to nonsocialist countries; and our domestic sales were also greater than planned. In this year--the base year of the Sixth Five-Year Plan--we have strengthened our market situation and the position of our enterprises, but we know that we can maintain this only with further efforts.

It is a fact that in the Fifth Five-Year Plan we wanted significantly to increase the production of wool and silk fabrics, and shoes. We kept modifying our ideas for 2 years, because in this field the commodity relations with regard to materials and finished products are not favorable. We will not be able to change this in the Sixth Five-Year Plan either. And let me draw attention to the fact that in the Sixth Five-Year Plan we will not limit the branch, but only the production of inefficiently made goods. It is a basic change: that in order to meet the plan goals we will not make use of investments but of cost-saving development methods (for example, organization and cooperation). We estimate that for the production of the same quantity of goods we will have less manpower available, but because of the efficiency requirements themselves we will be hiring fewer workers, and we will also be reducing the number of nonworker positions.

[Question] How will the sub-branch manage with the product change? How will the earlier programs be graded, that is, what ideas will have to be changed, and what areas will these affect?

[Answer] The work of the clothing industry is dictated by style; in adjusting to the seasons, it alters the product structure twice, and every 3 or 4 years it changes it completely. It is an economic disadvantage that we must import 80 percent of our materials, but in the rapid change of products this is an advantage. We can more freely and readily select raw materials for a given altered product structure than countries that are self-sufficient. Of course, this does not mean that all old products are unmodern or all new products are modern. There is still much to do in this area. In the Sixth Five-Year Plan it will remain a central task to speed up the modernization of products.

In 1979 our enterprises prepared strategic plans for the modernization of the product structure. In accordance with the new prices, the new price mechanism, the market situation, and our efficiency, we have developed new

priorities. We shall examine in turn also the concepts of our more important industrial branches. That is, the enterprises and ministries will primarily correct the market, production and production development goals from the viewpoint of economy. For example, in previous years the Hungarian silk industry was not export-oriented. This situation has changed. Since the reconstruction, 63 percent of our fabrics are made on modern machinery. In 1979 it developed only half as many new products as in 1977, but much more successful ones. With a Swiss license we introduced five new goods in 40 new patterns and solved the problem of finishing nonshrinkable lining. We have begun making moisture-absorbent blouse material from synthetic materials, and light weight curtain and drapery materials, which for a long time were in short supply, are now available in stores. On the other hand, we looked in vain for stylish corduroy and velvet. Imports have declined and the customers are complaining. To meet the demand, the manufacturing firm, the Cotton Textile Works, has modernized, and the corduroy supply has improved. But demand has grown faster than our development possibilities--this year, for example, the furniture industry alone uses as much corduroy as the domestic trade puts on sale--and therefore the supply is still not free of disruption. We ease the shortage to an extent with less expensive, stitched corduroy.

In the Sixth Five-Year Plan we can and we must overtake the modern manufacturers. To do this, we have asked the enterprises to broaden their selection, pay closer attention to the demands of the buyers, and carry out product developments more rapidly. It is not necessary for us to act in isolation, for we are stimulating the production development of the fabric-producing enterprises, the ready-to-wear, the knitwear, and the thread manufacturing, shoe manufacturing and leather industrial enterprises. In this collaboration there are many possibilities and important potential reserves.

[Question] How do the profits of the sub-branch stand as we approach the threshold of the Sixth Five-Year Plan? Will there be elimination procedures, and in which enterprises, despite all intervention attempts, has it not been possible to put management in order from the financial point of view?

[Answer] The five-year plans have always been accompanied by changes in the economic regulators. This is how it stands now too. It is an advantage that we have already introduced in 1980 the regulators for the Sixth Five-Year Plan. After the trial year, we shall see where it needs correction and in what respect when the medium-term plan is started. It is well known that the regulation introduced in 1980 substantially altered the profit situation of the individual industrial branches and enterprises. For example, the profits of the home textile enterprises declined by about one-tenth, while those of the leather factories increased several fold.

But lower profits as a whole have put into a difficult situation a number of enterprises and industrial groups (for example, the wool industry enterprises) the exports of which were not efficient enough, and which must now also balance their large-scale development debts incurred in the past years.

On the basis of 1979 results, we have found, together with the Ministry of Finance, 12 low-efficiency enterprises, and recent investigations show that six of these have successfully carried out the plan measures; they have assured management conditions for 1980, and there is no need for central measures. We are continuing to examine the management of the six remaining enterprises, because it is expected that in 1980 they will have fund-shortages or deficits. We will not permit the consequences of weak management to be prolonged for years and deficits to be repeated--for this reason it may be expected that the affected enterprises will be eliminated.

And still we may say that the vast majority of the enterprises not only understand the requirements of the new regulators very well, but adjust to them better all the time. This is shown by the fact that the results of the first half year are better than we estimated on the basis of the first quarter.

[Question] Finally, outline for us the perspectives of the sub-branch, with particular regard to the changing world market conditions system which is sometimes favorable. Is the plan for the branch's Sixth Five-Year Plan period ready? And in its main outlines, what does it include?

[Answer] The most important fact is that in the next decade the population will expect at least as many goods as nowadays. But they will ask for better quality and more style. Basically, this defines the future of the clothing industry. We can rest assured about the contracts as well: the international agreements for the Sixth Five-Year Plan period have already been signed with the socialist countries, and according to these our shipments will not be decreased. We are planning an increase in our nonsocialist exports, counting on a world market situation that will make this possible.

The development of the knitwear, ready-to-wear, dry goods and leather goods industry will be faster than average, although we will decrease somewhat our cotton thread production. We shall try to produce a better, finer thread than now. Meanwhile, the knitting and weaving industry that uses 25 to 30 percent of the wool fibers. In the wool fiber industry we are creating the conditions for the spinning of special pattern fibers and the full processing of Hungarian wool; we are producing more and better carded fabrics; and we are seeking to bring about--on the basis of the resolution by the Council of Ministers--a significant improvement of quality in the shoe industry.

BRIEFS

NATURAL GAS IMPORTS--Though Poland, with a production of 18.5 billion cubic meters of gas, occupies 15th place on the list of the world's largest producers, the foreign deliveries of that raw material grow from year to year. At present, we import nearly 4 billion cubic meters of natural gas, which consumes 860 million foreign exchange zlotys, and this is the seventh item, from the standpoint of expenditures, in our imports. Whether or not the economy will feel the marked progression of expenditures for this purpose depends on the development of our own production of the native gas deposits exploration, and also on the further cooperation in the development of the extraction support base of the chief supplier of gas in our country. LOW PRICE REDUCES SUGAR BEET ACREAGE, PRODUCTION

Belgrade PRIVREDNI PREGLED in Serbo-Croatian 30 Aug-1 Sep 80 p]

[Excerpt] This year the sugar beet harvest will soon begin under slightly unusual circumstances. There are no longer the problems that existed for several years of large reserves of sugar and inadequate storage space. Now it is a question of insufficient acreage having been planted in sugar beets at a time when the Yugoslav sugar industry has increased its production capacity.

This year, in addition to the 18 existing sugar mills, new sugar mills in Ormoz and Bijeljina will begin operating, and test production will begin at the sugar mill in Virovitica. Repairs in sugar mills have been completed, so that all 20 are fully ready for the coming campaign. At present the market situation at home and abroad is also very good.

But sugar beet production is stagnating. According to the "Jugosecer" business association, only 128,000 hectares were planted in sugar beets this year but some of this was destroyed by bad weather, so 126,495 hectares remained.

The situation is especially bad in Macedonia and Kosovo and this has been the case for several years. As a result, the mills in Bitolja and Pec will not be able to meet even one-half of the need.

At the moment the status of the sugar beet crop is satisfactory. Thanks to favorable weather conditions, a good sugar content is expected. If the weather continues to be favorable and a sugar content of 13.2 percent is attained (as last year), 5.6 million tons of sugar beets could be produced (compared to 5.8 million tons last year), which would yield about 740,000 tons of sugar, or the amount needed to meet domestic market demand. (In addition to the lack of sugar beets, sugar mills still are in need of sugar bags for packing.)

The cause of all this misfortune is the price disparity between sugar beets and grain, primarily wheat. This year's price of 0.70 dinars per kilogram

has obviously not been an incentive for increasing production. During the planting period itself, the price was seen to be so low that sugar factories were forced to raise it to 0.90 dinars per kilogram. Even so, 1,300 hectares less were planted than last year.

In 1976 the price ratio of wheat compared to sugar beets was 1:3.8, while this year 4.60 dinars were paid for a kilogram of wheat and 0.70 dinars for a kilogram of sugar beets, bringing the ratio to 1:6.6. "Jugosecer" considers it necessary to return to the ratio of 1976 in order for installed capacities to be utilized.

CROP CHANGES PLANNED IN MACEDONIA UP TO 1985

Belgrade PRIVREDNI PREGLED in Serbo-Croatian 23-25 Aug 80 p 6

[Article by G. Dimovska: "Optimum Guidance"]

[Text] In every development program to date of the Socialist Republic of Macedonia considerable attention has been devoted to agriculture, which is no accident, since more than a third of the total population derives its living from farming. Moreover, the climatic conditions for a particular product signify an advantage over other parts of the country, and the time has passed when Macedonian farmers were by and large producing in an unorganized way to meet their own needs. Today their basic production orientation is to produce for the market, taking advantage thereby of comparative advantages and giving preference to products on the basis of the income they bring. That is why there is the steady switchover from grain to vegetable and industrial crops in terms of area planted.

Industrial crops offer Macedonian agriculture a good future, especially because over the last several years so to speak all the necessary prerequisites have been provided for their intensive development. Irrigation systems cover 130,000 hectares of arable land. The private and socialized sectors of agriculture already possess about 15,000 tractors, and the climatic conditions, assuming intensive irrigation, are better than favorable to these crops.

Over the last 5 years agricultural combines and private farmers have been paying the greatest attention in their development plans to industrial crops. According to their estimates, procentual increases in output between 1979 and 1985 would be about 140 percent for sugar beets, 91.3 percent for sunflowers, 259 percent for poppy seed, and 110 percent for cotton.

We should emphasize that results of this kind would be achieved by increasing the area planted to these crops, but also by raising yields, assuming better collection of seed material, more intensive application of scientific soil and crop practices, mechanization, etc. It is also very important that the food processing industry expects a great deal from the development

of industrial crops; at present, because of the lack of sugar beets and sunflowers, it is compelled either to use only half of the existing production capacities or to make up the shortages to some extent by importing related crops. Soybeans are an example of this.

The Promise of Cotton

As for cotton, the situation is specific. In spite of the expected and obvious increase in its production over coming years, the textile industry in the country cannot count on any sizable substitution of imported cotton by domestic cotton, since the analyses made to date have established that we cannot expect any major increase in cotton production, and the reasons are objective.

The region of Macedonia has a geographic position which allows for this crop to be raised successfully. In the well-known regions where cotton is raised, such as Pakistan, India, Egypt, Sudan, the southern portion of the USSR and certain other countries, as many as three harvests are taken annually. There the average annual yields are between 2,800 and 3,000 kg per hectare, while in the socialized sector in Macedonia they rarely exceed from 1,200 to 1,500 kg. In the private sector the average yields range about 800 kg.

Given this situation, the producers have calculated that their cost price is about 21 dinars per kilogram, and everything below that would in practical terms signify a loss. Today the support price per kilogram of first-class cotton is 13 dinars, and 14.30 dinars is paid on the market. In practice, however, second-grade cotton is the most common, and its price is 2 dinars less per kilogram than the first grade, so that the question is how to increase production over the next 5 years.

The producers are counting on higher yields and also rises in both world and domestic cotton prices. That is why they plan an increase from the present 1,579 hectares, producing 1,420 tons of cotton annually, to 3,000 hectares planted to this crop in 1985, and an annual output of 3,000 tons. Yet this amount is enough to meet the needs of one medium-sized spinning mill.

A More Favorable Situation for Sunflowers and Sugar Beets

The prospects for sunflowers are considerably better. Today they are being raised on 20,942 hectares, and another 11,000 hectares will be added over the next 5 years. If we take into account the planned rise of the yield per hectare from the present 12 quintals to 15.6 quintals per hectare, then we see why a total annual sunflower output of about 50,000 tons is expected in 1985. This is actually the amount needed by the Blagoj Djorev Mill in Titov Veles if it is to produce vegetable oil and margarine at full capacity.

A definite guarantee to fulfillment of the plan is that firmer cooperation has recently been established between this mill and sunflower producers. They are undertaking relations based on shared income and sufficient incentives for the production of this crop. Macedonian sunflower producers judge that production could increase still more dynamically than called for in the development plan, since the potential in terms of yields is very great, especially since the region with the greatest capability for sunflower production, the Pelagonian Basin, will in a few years have the Strezevo, the largest irrigation and drainage system in the republic.

The situation is similar with sugar beets. In 1979 it was planted on 3,454 hectares with average yields of 354.4 quintals per hectare, and the harvest was 115,575 tons. Five years later the area planted to this crop should be 6,500 hectares, the yield should rise to about 420 quintals per hectare, and the annual harvest should be more than 250,000 tons of sugar beets. This production would give the 4 November Sugar Mill in Bitol a full guarantee to operate at full capacity. Which accounts for its all-out effort to encourage the farmers to produce more through additional incentives in the purchasing of beets, favorable credit terms, free seed, technical assistance, machinery and so on.

The development plan for the republic's agroindustrial complex also shows that private farmers will be devoting more attention to the production of poppy seed. In 1985 poppies are to be raised on 6,500 hectares, which is 3.5-fold more than in 1979. Of the total area planned together with the socialized sector, which is 8,000 hectares, the annual harvest should be about 5,600 tons of poppy seed. This will be a sizable base for the food processing and pharmaceutical industries.

BRIEFS

HARD CURRENCY TO RAILROADS--All organizations of associated work which use the services of foreign railroads to export or import goods will have to pay for these services in foreign exchange beginning on 1 September. This is as stated at a 25 August press conference held at the Yugoslav Railroads, in accord with a FEC (Federal Executive Council) decision issued in July. Danilo Fogel, member of the business council of the Yugoslav Railroad Association, said that this decision means that he who creates foreign exchange obligations must also pay for them. It has been different up to now. The Yugoslav Railroads have paid for the obligations of others. Up to 1979 the railroads earned more foreign exchange than it spent, but last year because of the sudden increase in the number of users of these services it got into a difficult situation. Now when we are starting to apply the FEC decisions, users themselves will directly pay their foreign exchange obligations; this will contribute toward reducing imports, since up to now importers could import more goods because the transport costs were paid by others. Last year importers could import about $100 million more in this way. This [new ruling] will have little effect on [train] passengers who will continue to pay for their tickets out of the country in dinars, while the republic and provincial self-management interest communities for economic relations with foreign countries will provide the foreign exchange funds. Although the new system of settling foreign exchange obligations began to be applied on 1 July, only a few began to transfer foreign exchange to the railroad transportation organizations. Now everyone will have to do this, and sanctions are planned for those who fail to comply. [Excerpt] [Belgrade BORBA in Serbo-Croatian 26 Aug 80 p 14]

EXCESSIVE BUREAUCRACY--Where and how can one economize? In seeking the answer to this question one most often arrives at the problem of administration. In the estimate of many, administration has multiplied to such a degree that it goes beyond the possibilities of associated work and has become one of the limiting factors to further development of labor productivity, efficiency, and rational economic operation. Let us mention only the self-management interest communities where more than 41,000 are employed. No one complained that the number of persons employed in secretariats and professional services in sociopolitical communities [Federation, republics, provinces, opstinas] be reduced by this number as was proposed when the self-management interest communities were formed. Of course this is not the only

place where there is an overpopulation of administrators. At present 5,082 functionaries and other professionals are employed in the LCY, i.e. for every 300 members approximately, there is one "administrator." This number is growing from year to year; last year the number increased 5.4 percent over 1978 when there were 5,389 people employed in the professional apparat of the LCY. [Excerpt] [Pristina JEDINSTVO in Serbo-Croatian 19 Aug 80 p 4]

U.S. BANK CREDIT TO SPLIT--An agreement was signed in Split with one of the ten largest American banks, the Marine Midland Bank of New York, granting a $10 million credit to the Bank of Split for a period of 7 years (plus a 30 month moratorium). The credit will be used to finance investments already underway of account-holders at the Bank of Split. In the last 2 years this U.S. bank has granted over $25 million in long-term credits to pay for imported equipment. The bank in Split is also using $12.5 million in short-term credits which the New York bank granted to import producer goods and various consumer goods. The agreement was signed by C. Norman Hansen, vice president of the New York bank, and Jovica Kunac, director of the Bank of Split. [Text] [Belgrade PRIVREDNI PREGLED in Serbo-Croatian 27 Aug 80 p 12]

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

NATIONAL ENERGY SITUATION, DEVELOPMENT DESCRIBED

Warsaw PRZEGLAD BUDOWLANY in Polish No 6, Jun 80 pp 323-325

[Article by Lechoslaw Gruszczynski, Undersecretary of State in the Ministry of Power Industry and Atomic Energy]

[Text] Past development of Poland's power industry

During the 35-year history of the Polish People's Republic electric power production increased 20-fold, which has put our country in second place among the CEMA countries, in sixth place in Europe, and tenth in the world.

Important qualitative changes have been made, indicated by substantial technical progress, reduction in unit fuel consumption and public resources for construction and operation of power facilities, and decreased negative impact of power plants and electric power and heat generating plants on the environment.

National growth in generating capacity and electric power production during 1970-1980 is reflected in the following figures:

	1970	1980 (planned)
-- generating capacity, MW [megawatts]	13,890	26,000
-- capacity increase, percent	100	187
-- electric power production, GW·h [gigawatt hours]	64,500	125,000
-- production increase, percent	100	191

The centralized heating-plant system also expanded rapidly and is now one of the largest in Europe.

Growth in public-utility power industry capacity for thermal energy production during 1970-1980 was as follows:

	1970	1980 (planned)
-- attainable thermal capacity, MW	7,670	21,000
-- capacity increase, percent	100	273
-- thermal power production, GJ [gigajoules]	$75,882 \cdot 10^3$	$215,600 \cdot 10^3$
-- production increase, percent	100	284

Consumption of basic fuels by the public-utility power industry during 1970-1980 was as follows:

	1970	1980 (planned)
-- hard coal, thousand tons	24,385	58,240
-- consumption increase, percent	100	239
-- brown coal, thousand tons	26,636	35,200
-- consumption increase, percent	100	132

The public-utility power industry is the country's largest coal consumer. In 1979 it used 54,432 thousand tons of hard coal, or 27 percent of the national output.

Brown coal, as an energy-producing raw material, in 1979 supplied about 20 percent of the heat contained in fuels consumed by the public-utility power industry.

Liquid fuel consumption, allowing for world market difficulties, accounted for three percent of the heat contained in fuels used by the public-utility power industry.

During the 1970's, the public-utility power industry made great strides in improving the efficiency of electrical and thermal power production. This is illustrated below:

	1970	1979
-- standard fuel unit consumption rate for gross electric power production kJ/kW·h [kilojoules per kilowatt hour]	10,959	10,580
-- electric power consumption rate for own needs, percent	7.39	7.17
-- standard fuel unit consumption rate for thermal power production, MJ/GJ [megajoules per gigajoule]	300.6	292.3

Reduction in standard fuel unit consumption was achieved by start-up of more efficient generating units, particularly 120 and 200 MW power units rated at 10,000-10,500 kJ/kW·h; converting old power plants into electric power and heat generating plants; and building new electric power and heat generating plants producing electric power at 4,840-4,980 kJ/kW·h.

Generating capacity is now provided by 120, 200 and 500 MW power units, in which about 70 percent of total public-utility power capacity is concentrated.

Poland has one of the best standard fuel unit consumption rates in Europe.

The present national energy situation and future developments.

Thorough examination has revealed that recent energy problems in our country are traceable to the following causes:

-- recent disproportion between available capacity of power plants and the gradually growing consumer demand for electric power,

-- inadequate technical progress in the field of efficient and economical energy consumption.

It should be emphasized that during the 1970's there were significant developments in all areas of the national economy, causing a large increase in demand for power. But this increased demand was not accompanied by equivalent increases in indispensable power generating capacity, and due to lack of preventive maintenance, the availability rate of existing generating equipment dropped. This was attributed to insufficient spare parts manufacturing potential and lack of conversion capacity during repairs. As a result the imbalances in electric power availability increased, which made it necessary to restrict supplies of power to consumers.

The energy situation became particularly bad in 1979. After serious problems during the first quarter, caused by unfavorable weather conditions, it became necessary to restrict power deliveries to consumers until October 1979.

A number of measures were taken to control this difficult situation. They included issuing a decision to integrate the production of power machinery and equipment with power industry construction in order to make the investment process more efficient and to improve the repair service.

The first positive results of the reorganization and other actions appeared at the end of the fourth quarter of 1979 and in the first quarter of 1980. Restrictions on power supplies to consumers were greatly reduced and the energy situation was finally alleviated.

But the power industry must undergo further systematic comprehensive improvement if it is to supply the country with adequate electrical energy.

To ensure a fuel-energy base to 1985, we must:

-- allocate 73 million tons of hard coal, out of an increased extraction of 232-235 million tons annually, to the public-utility power industry,

-- increase extraction of brown coal to 80-90 million tons annually (a more than 100 percent increase in extraction over 1980),

-- increase electric energy production to 160-168 GW·h,

-- raise attainable generating capacity to a level of 37,000-38,000 MW.

In Poland the main source of energy is, and will continue to be, coal.

Recoverable reserves of coal in Poland can provide hard coal for a long time, but the difficult accessibility of deposits increases technological problems in mining and extraction costs.

Because of this, hard coal mining will require greater outlays for modernization of existing mines and construction of new ones. Thus it is essential that hard coal be used efficiently and economically.

Given these circumstances, intensive development of brown coal extraction is one of the main courses of action. It is envisaged that brown coal's share in satisfying the public-utility power industry's fuel requirements will increase from 20 percent in 1980 to 30 percent in 1985. Extraction will increase from a planned 40 million tons in 1980 to 80-90 million tons in 1985, to be realized mainly in the Belchatow mine now under construction.

Construction of brown coal mines in Szczercow and Legnica in the next few years is anticipated. This should, by 1990, triple 1980 extraction figures.

Such a rapid rate of brown coal extraction will require very large outlays for construction of machinery and equipment for strip mining.

Construction of the first nuclear power plant in Poland, within the framework of CEMA-country agreements, will take place during 1981-1985. The power plant will have an ultimate generating capacity of 1,880 MW (2 x 440 MW + 1,000 MW).

The construction of the next nuclear power plant will also begin; these power plants will initiate the development of Poland's atomic power industry.

Needless to say, the introduction of nuclear energy will require much new technology dealing with production of equipment and power plant construction and operation.

The rate of increase of electric power production by nuclear power plants during the next decade will necessarily be limited by the need to gradually introduce new techniques.

Only two percent of the country's electrical energy in 1979 was produced in hydroelectric power plants. Although water resources are being utilized to a very large degree and a doubling of production by 1990 is envisaged, improvements in hydroelectric power plant are limited.

In examining plants for future development in the national energy situation, problems involved in balancing all types of energy must be considered, including consumption of energy contained in raw materials as well as generated power, i.e., electrical and thermal.

Efficient utilization of energy is predicated on determining the optimum level of consumption of all types of energy. In making this determination it should be recognized that the efficiency of generating electrical energy in steam generated power plants is very low, about 33 percent, and the feasibility of increasing this efficiency is very limited due to the thermodynamics of the process. Therefore, the selection of energy used in each industry should be thoroughly examined.

To achieve the national energy balance projected to 1990 and future years, certain courses of action for specific groups of energy consumers have already been defined.

For example, in the Ministry of Construction and Construction Materials Industry, plans for using different energy sources will unquestionably produce considerable reductions in energy consumption. This Ministry's basic courses of action will be to improve the thermal insulation rating of buildings and accommodations and to introduce new, more efficient technologies in the production of construction materials.

Conclusions

1. Our present state of energy management requires, besides expansion of the fuel base by increased brown coal extraction and higher power plant generating capacity, more efficient use of fuel and energy.

2. Supply and demand for electric energy can be balanced in 1985 if:

-- fuel and energy utilization efficiency improves substantially,
-- brown coal extraction increases by more than 100 percent over 1980, and
-- generating capacity in power plants and electric power and heat generating plants increases by 11,000 MW.

FINAL ACCOUNT OF 1979 FEDERAL BUDGET

Belgrade SLUZBENI LIST SFRJ in Serbo-Croatian No 42, 25 Jul 80 pp 1365-1412

[Final account of the federal budget adopted by the SFRY Assembly in a session of the Federal Chamber on 17 July 1980]

[Text] I. General Section

Article 1

Revenues collected and the distribution of revenues in 1979 are as follows:

1) sum total of revenues collected according to the balance sheet of the federal budget	102,028,525,245.25 dinars
2) sum total of distribution of revenues according to the balance sheet of the federal budget	101,984,334,094.10 dinars
3) difference between total revenues collected and total distribution of revenues according to the balance sheet of the federal budget	44,191,151.15 dinars
4) total surplus of revenues over distribution	44,191,151.15 dinars

Article 2

The surplus shown in Article 1 of this final account, amounting to 44,191,151.15 dinars, shall be transferred to the permanent federal budgetary reserve.

Article 3

Following are given a tabulation of anticipated and actual revenues and a tabulation of anticipated and actual distribution of revenues in the Balance Sheet of the Federal Budget for 1979:

I. Revenues

Revenue Form 1	Revenue Sub-form 2	Revenues 3	Anticipated by Budget 4	Anticipated Adjusted Budget 5	Actual 6
		Type 03. Turnover Tax on Products and on Fees for the Rendering of Services			
03-1		Turnover tax on products	38,203,900,000	38,203,900,000	37,699,592,616.00
	03-1-1	Portion of the basic turnover tax on products	38,203,900,000	38,203,900,000	37,699,592,616.00
		Total Type 03. Turnover Tax on Products and on Fees for the Rendering of Services	38,203,900,000	38,203,900,000	37,699,592,616.00
		Type 05. Fees			
05-1		Administrative fees	129,000,000	129,000,000	167,705,146.27
	05-1-1	Consular fees	66,000,000	66,000,000	115,899,795.45
	05-1-2	Customs fees	57,000,000	57,000,000	48,298,251.62
	05-1-3	Other federal administrative fees	6,000,000	6,000,000	3,507,099.20
05-3		Court fees	1,000,000	1,000,000	1,004,428.50
		Total Type 05. Fees	130,000,000	130,000,000	168,709,574.77

I. Revenues (continued)

1	2	3	4	5	6
		Type 06. Customs Duties and Special Charges			
06-1		Duties	9,367,860,000	11,587,460,000	10,512,182,232.72
06-2		Special import fees and charges	12,513,540,000	12,513,540,000	14,078,837,491.02
	06-2-2	Special charge to equalize the tax burden	4,435,740,000	4,435,740,000	5,032,419,997.10
	06-2-3	Charge for customs record-keeping	813,220,000	813,220,000	896,584,649.73
	06-2-4	Special fee on imported commodities	7,243,460,000	7,243,460,000	8,147,857,917.06
	06-2-5	Storage charges on goods kept in bonded warehouses	21,120,000	21,120,000	1,974,927.13
		Total Type 06. Customs Duties and Special Charges	21,881,400,000	24,101,000,000	24,591,019,723.74
		Type 07. Revenues Under Special Federal Statutes, Revenues of Administrative Agencies and Miscellaneous Revenues			
07-2		Revenues of administrative agencies	1,539,000,000	2,119,000,000	2,076,468,786.43
	07-2-1	Revenues of federal bodies, agencies and organizations	1,539,000,000	2,119,000,000	2,076,468,786.43
07-4		Miscellaneous revenues	767,900,000	767,900,000	605,034,544.31

I. Revenues (continued)

1	2	3	4	5	6
		Total Type 07. Revenues Under Special Federal Statutes, Revenues of Administrative Agencies and Miscellaneous Revenues	2,306,900,000	2,886,900,000	2,681,503,330.74
		Type 08. Revenues From Other Sociopolitical Communities			
08-1		Contributions of the republics and autonomous provinces	28,436,300,000	28,436,300,000	28,436,300,000.00
	08-1-1	Contribution of the Socialist Republic of Bosnia-Hercegovina	3,615,200,000	3,615,200,000	3,615,200,000.00
	08-1-2	Contribution of the Socialist Republic of Macedonia	1,584,900,000	1,584,900,000	1,584,900,000.00
	08-1-3	Contribution of the Socialist Republic of Slovenia	4,636,200,000	4,636,200,000	4,636,200,000.00
	08-1-4	Contribution of the Socialist Republic of Serbia, not including autonomous provinces	7,013,600,000	7,013,600,000	7,013,600,000.00
	08-1-5	Contribution of the Socialist Republic of Croatia	7,667,200,000	7,667,200,000	7,667,200,000.00

POLITICAL SCIENCE PROFESSOR DISCUSSES ECONOMIC SYSTEM

Belgrade RAD (organ of the SSJ [Federation of Yugoslav Trade Unions]) in Serbo-Croatian No 35, 22 Aug 80 pp 4-5

[Interview with Dr Zivojin Rakocevic, professor of political economy at the School of Political Science of Belgrade University: "Marx's Image on the Dinar"; date and place not given]

> [Text] Last year, and especially early this year, our economy has suffered many misfortunes, some because of domestic weaknesses, others because of imported inflation. Administrative measures have come one after another, accompanied by crash efforts of the workers to stabilize the business operation of their organizations. And the second package of measures by the Federal Executive Council is in the offing, but even this, of course, does not presage a much deeper undertaking in the socio-economic system, the correction of the consequences of disturbances in the market. Science has still not said its piece about the causes of the situation in our economy, at least not in the form of an overall analysis of the shortcomings of the domestic economy. One of those who feel that it is inevitable that science judge the causes of our economic circumstances (troubles) is Dr Zivojin Rakocevic, professor of political economy at the School of Political Science in Belgrade. Through his collaboration with many political forums he has had occasion to "hear of" the problems of production workers and the peasantry in the conduct of economic activity. From a conversation with Dr Rakocevic we are presenting some of his conceptions concerning the faults and virtues of our economy in what are called either-or situations.

[Question] What is the deepest cause of the problems in our economy?

[Answer] Relative prices are in my opinion the most complicated economic problem both in our economy and also in economic science. As a matter of fact, even in political economy there is quite a bit of confusion in interpreting relative prices, since this issue is debated with differing and even altogether opposed theoretical weapons. According to Marx, relative prices are modified market values of goods, the real relationship of absolute values which depend almost entirely on the live and past labor they embody.

[Question] It seems fairly simple....

[Answer] But it isn't. Many things in the movement of relative prices depends on the monetary measurement of prices and on who determines this. Which is why all those things happen which have not been sufficiently elucidated even from the scientific point of view. I am referring primarily to the role and function of the central bank, to the way the rate of exchange is implemented, to the way dinar convertibility, an aim adopted in the reform, is being pursued, if it is.

[Question] Well, has there been success in maintaining that course, which since the economic reform has seemed inevitable, or hasn't there?

[Answer] Not entirely. I even have the impression that there is a retreat from that course in every either-or situation. What is more, the central bank finds rather convenient excuses for this fudging, and I feel that this is precisely the deepest source of our economic troubles, especially those related to prices. It is a scientific truth that our banking system is predominantly governmental, that is, that it is under the wing of government political power, and that holds from the opstina to the Federation. If we remove the outside wrapper and ascertain precisely where the productive work is and where the economic power is, we would reach the conclusion which Marx framed long ago: we have gone too far in our carefree living off future production, and it is the direct industrial and agricultural producers who have done less of this than anyone else. The bankers ought to be more responsive to the demands of physical production, even at the price of displeasing the federal government.

[Question] How similar are the events in our economy to "Marx's market"?

[Answer] It seems paradoxical, but our market has never seriously befriended Marx. What is "operative" for us is the Keynesian theory from the thirties of this century, which even today is the leading theory in the world economy, especially in the West. It has come into our practice and into the practice of the East European countries, though their official spokesmen deny it. For all practical purposes the doctrine of Keynes is applied in a wrapping marked "Marx's market," and the consequences of the overemphasized national economies demonstrate the kind of doctrine it is.

[Question] From the standpoint of theory do we owe the credit for relations on our market to a single scientist, or are these relations a mixture of several economic premises?

[Answer] They are a mixture of various theories and processes, as is indeed the case everywhere in the world. As a general thing no nation's economic life measures itself against a theory accepted as doctrine. At least so the official spokesmen of economic policy assert. In practice, though, the economy of every market is managed, at least in aggregate terms, in accordance with some doctrine, but this is skillfully covered over by a flood of experiments with new theories. Even we are involved in experimentation. The trouble is not with experimentation per se, but with the lack of a sufficiently critical attitude when tests are made of experiences and theories which are opposed to one another. There is hardly even a mention of experimentation along the lines of Marx's ideas. To be sure, no one states this in public, but it seems as though Marx's doctrine is sufficient to us in the sense of political ideology, while Marx has no instructions to give us in the economic sphere.

[Question] The stabilization measures have proclaimed the economy's return to economic criteria in the conduct of business....

[Answer] The so-called value principles in the economy were officially proclaimed as far back as 1965, that is, in the economic reform. There was also talk at that time about establishing the convertibility of the currency, but not, of course, with the ambition of the dinar's becoming a currency of world significance, but so that its real value on a world scale would be found. If we do not carry out that sound conception at the present time, we will lose almost any possibility of taking part in the witches' dance of international market relations. However, money is still what the government says it is, and it has the value which the central bank considers is realistic. We also have been inclined toward this creation of state capitalism.

[Question] Are you referring to science as well?

[Answer] I am referring particularly to our science, which rarely is a research topic it examines with its magnifying glass. It is not even a secret that we are waiting around for the large economies to solve this problem first, and then we will see how we will treat the problem of money and what we will do about it. To be sure, monetary specialists have offered the idea of creating an "alternative currency" which would be valid for all the developing countries and with which they might compete on a more or less equal footing with the dollar, the mark and the pound. Perhaps this would help tht economically weaker countries to become part of the international monetary system more easily.

[Question] Isn't this just another hurdle in the attempt to alter the economic order in the world?

[Answer] Nevertheless, it is interesting as an idea, and I am surprised that nothing has been done to put the theory into practice. What is more, it seems that ideas themselves have dried up. For instance, it has not even been raised as an issue what sort of connection there would be between the "alternative currency" and the laws of world commodity production and whether it would be managed by the government like the Western currencies.

[Question] Do you feel that in the resolution of economic problems there is in general an evasion of science?

[Answer] I would not say that it is evaded, but those in a position to apply it are not showing an excessive desire to do so. I am even persuaded that there is no Chinese wall between the economy and science, though there are pragmatic notions to the effect that the economy can be run without any science at all. Politicians who have become disappointed with false science, and have not looked further, are inclined to such conceptions.

[Question] For which we have paid dearly....

[Answer] Very dearly. I think that the economy will be paying tribute to that kind of prejudice for a long time yet. However, I also blame my colleagues for not sufficiently honoring the truth of the results they obtain, in short, for being timid. I feel that the truths about the results of scientific research should be presented in public, even though this may not be to the liking of the proponents of official economic policy and even though it may result in open debates and even disputes. Not for the sake of science, but for the sake of the health of the domestic economy. The conceptions of science should be defended on their own merits, and not with political pragmatism. Unfortunately, there are scientists who substantiate and justify administrative measures which government agencies have cooked up behind closed doors. When science puts on such clothes, it does discredit both to itself and politics. For example, there are as many different opinions as there are republics and provinces concerning the level of economic development and concerning economic relations among the federal units. That being the case, one might well doubt the disinterestedness and effectiveness of science in economic affairs.

[Question] Is it at all possible to create a "federation of markets"? That is, it seems that there are independent markets within the borders of the republics and provinces, all in the context of the "unified Yugoslav market."

[Answer] The two do not go together. Convertibility of the dinar is a condition for the stability and unity of the Yugoslav market and for its inclusion in international economic flows. With eight markets we have, though tacitly, eight values of the dinar, and even the stronger of our regional economies would not survive with that kind of situation. My opinion is just the opposite of the official position. The opposite, for instance, of the thesis of the central bank, which says that a stable rate of exchange

cannot be maintained, nor the convertible dinar created--because prices are unstable and because investment spending is excessive. But it is precisely because the dinar is not convertible and because the economy is living on credit that society's abstract wealth is being pumped up, and that is why we have excessive investment spending.

[Question] How, then, is the dinar to be strengthened in the international context?

[Answer] It is logical for social capital to "flee" a currency that has lost value, shelter is taken where it can be found, usually in a foreign currency. That is the beginning of the story about our export "boom." We celebrate, with good reason to be sure, when our people carry out construction projects in the outside world, but this kind of pursuit of a stronger currency is a consequence of the worthlessness of the dinar. Thus our capital "flees" to the more stable currencies, circulates in other national financial climes, and there it grows. At home, where credit capital is easy to get, particularly if some factor outside the economy exerts "pressure," capital is transformed into fixed assets. That is the origin of the exaggerated investment spending which has pretty much closed the doors of the world to the dinar.

[Question] Recently even our banks have not been exactly liquid....

[Answer] No, they haven't, since up until the official devaluation indolent behavior prevailed in business life: carefree borrowing from the banks up to the very point of the economic limit on credit. Devaluation was inevitable--so that foreign indebtedness would become less attractive, at least temporarily. The debt limits this year have been set at $2 billion, though the republics and provinces insisted on twice that. I think that we should do something to lay bare the makeup of that indebtedness, its sources, its forms, the terms and the rates of interest. An accounting must be rendered concerning this, next year if not before, since the next agreement on the balance of payments pertains to the economy in the new medium-term planning period. It is now that we are seeing confirmation of Marx's visionary prediction that any society involved in world market flows must fall into a crisis either-or situation when it must settle accounts with "God," that is, with the law of value as it applies internationally.

[Question] Since the devaluation of the dinar exports have been the almost universal formula for solving all problems. To what extent is the export euphoria economically healthy for the economy and for the stability of the dinar?

[Answer] No euphoria is healthy. I do not see why exports should be a general and magical formula for the way out of the economic crisis. I think that the export fever is a consequence of a one-sided examination of the problems in the economy: an examination conducted from the standpoint of the balance of payments. To be sure, exports are an important aspect of

economic life, but the export fever has already caused troubles for our market. Now we have the nonsensical play of fluctuating rates of exchange and a black market for foreign exchange. What is more, few people are concerned about whether exports are profitable. That is, if exporters are constantly offered larger premiums and are given various tax exemptions, then for all practical purposes they are being supported by those who produce goods exclusively for the domestic market. This is an unprofitable business and however quickly and effectively exports resolve the problems of the balance of payments, on the other side the problems in physical production will be compounded and complicated still faster.

[Question] Prices are frozen, and now associated labor is deciding on their fate....

[Answer] However nimbly the members of the Federal Executive Council speak about stabilization. offering all the arguments, the impression remains that the devaluation was undertaken without reliable economic calculations. They even say that they adopted those measures in order to sever relations in the economy which they judge to be wrong, not in conformity with the Law on Associated Labor. The paradox is that they boast of severing relations, but now they are leaving it to the economy to retie those severed threads. Moreover, it has turned out that the effects of this one-sided act were meager. I think that the strength of the associated production workers was underestimated and that at the very least it is no fair for them to be appealed to first to carry out the measures "from above," and then when the economy gets in an either-or situation, the government puts it up to associated labor to solve it. For many business executives the devaluation was like a thunderbolt from a clear sky, a well-kept government secret about the measures intended for the economy—which in and of itself is paradoxical. Moreover, the official spokesmen in the central bank are assuring the public that there exists a floating rate of exchange of the dinar. If that is the case, why was there an official devaluation at all, what is the reason to abolish the official interbank foreign exchange market such as we have had until recently?

[Question] What in your opinion is the way out of our present economic difficulties?

[Answer] If a change of direction comes about in conjuncture in the leading world economies, then they will be the locomotive which will also pull the other national oconomies. I am afraid that that is the only big exit door from the economic crisis for us. If we knew earlier what we know now, we might already have created a number of defensive mechanisms which would now mitigate the trouble with the world market. In 4 or 5 years the situation will be still more difficult unless we take advantage of the next medium-term planning period for qualitative changes in the technology of physical production and in primary distribution and to transfer the most important economic functions to associated labor. If greater difficulties are not to occur, stabilization of the economy cannot be reduced to a belt-tightening

for production workers and the peasantry. Only they can reaffirm the production of value and productive creativity and thus strengthen our economy.

[Question] As a scientist do you feel responsible for the situation in our economy?

[Answer] Yes and no. Yes, because I am involved in public affairs. No, because like a majority of my colleagues, I am not very often called upon. I feel that science could help the economy a great deal, but only if it examines even the most abstract economic issues "on the terrain." That is, if it relies on the economic backbone of the society--the producer part of the working class.

ROLE, GROWTH OF PENSION SYSTEM SURVEYED

Belgrade EKONOMSKA POLITIKA in Serbo-Croatian 4 Aug 80 pp 20-22

[Text] When it comes to disability and old-age insurance, it is relatively easy to carry out the announced reduction of social service expenditures in the context of the overall stabilization measures. The policy of a slower growth for personal incomes, since contributions are calculated by taking a certain percentage at a linear rate, will in and of itself reduce the growth of pension revenues. At the same time, bringing the growth of pensions into line with the growth of personal incomes instead of with the growth of the cost of living will also slow down the setting aside of funds for pensions. In that sense the pension as an economic category will be brought closer to the flows of production, and will be less hindrance to them than in the past. After all, as we know, appropriations for pensions and disability benefits have for years been growing faster than the growth of the national income, which among other things has had a direct impact on the ability of the economy to form capital, and thus ultimately it has encroached upon the income from which appropriations are made for this insurance.

As a social category, however, the pension has a role which is becoming more important under the new conditions of stabilization. It is necessary to preserve the existential level of pensioners when the growth of revenues for old-age insurance is slower and the number of old-age pensioners is increasing more rapidly. This unquestionably implies a more stringent policy concerning the granting of disability pensions.

The Growth of Pensions

Between 1946 and the end of 1978 the number of pensioners in Yugoslavia increased almost 12-fold, and the number of disability pensioners more than 11.5-fold. The growth of pension recipients in the total population increased over that same interval from 1.3 percent to 6.7 percent. Does this reflect demographic laws? Perhaps. But we should also be mindful of the other side of the consequences: between 1948 and 1978 the increase in the

number of pensioners was faster not only than the growth of the total population, but also faster than the growth of the labor force; which means, then, faster than the source of money for pensions. In that interval the increase in the number of pensioners averaged 1.9 percentage points faster than the annual increase of the number of insureds in the labor force. The situation was still more drastic by republics and provinces: the number of percentage points of difference between the growth rate of the number of pensioners and the growth rate of the number of insureds in the labor force was 6 in Macedonia, 5 in Montenegro, 3 in Serbia, 1.9 in Croatia, and 1 in Bosnia-Hercegovina. Only in Slovenia were these two rates approximately the same: the number of pensioners increased only half a point faster than the increase in the number of insureds in the labor force.

The number of pensioners has been increasing in waves. If we take the interval between 1948 and 1953 as the first wave, then it is relatively easy to find the coordinates of the largest influx of pensioners since the war in absolute terms. Over those 5 years pensions increased at an annual rate of 14.4 percent, and disability pensions had a large share in them. The reasons are understandable, the consequences of the war.

Average Annual Growth of the Total Number of Pensioners in Yugoslavia

Interval--Years	Growth, %	Interval--Years	Growth, %
1948-1953	14.4	1961-1971	6.9
1953-1961	6.4	1971-1978	3.3

However, those same consequences of the war, which brought about the huge number of disability pension recipients, brought about a change in the composition of the population to the advantage of the younger age groups; the average age dropped particularly because of the baby boom--a phenomenon which is also well known and which promised a further increase in the army of future insureds in the labor force within an age-specific composition of the population which was already young on the average.

The young labor force, as the number of new pensioners decreased, had the result that the next interval, between 1953 and 1961, was the only one in which pensions rose more slowly than the increase in the number of insureds in the labor force. However, it was in that interval that several statutes were adopted which have tended to alter that tendency--at first only in statistical terms. That is, under the Law on Disability Insurance recipients of disability benefits, who until that time had not been covered by the pension system, acquired that right, which thus tended to increase the growth rate of the number of pensioners. Between 1961 and 1971 the growth of pensioners was also intensive thanks to the drafting of the law on the possibility of early retirement. A new wave of pensioners, the second largest, occurred in the years between 1959 and 1964 and resulted from the use of pensions to resolve the problem of surplus manpower. The simplest solution was to award a disability pension, and the influx, the ever larger

number of pensioners, disability recipients above all, was not seriously affected by amendment of the law raising the pensionable age for old-age pensioners. (In 1964 a law was adopted which raised the pensionable age from 55 to 60 and years of service from 35 to 40 for men, and from age 50 to age 55 and from 30 to 35 years of service for women.)

The possibility of using disability pensions as a solution to various problems in the economy had the result, then, that disability pensions increased faster than old-age and survivor pensions, thereafter to be overtaken and slightly surpassed only by the wave of old-age pensioners resulting over the first 30 years after the war from the new demographic changes caused by the aging of the labor force.

Number of Pensioners Per 100 Insureds in the Labor Force

Type of Pension	1948	1953	1961	1966	1971	1978
Total 13.6	13.6	18.7	16.6	22.5	24.1	25.1
Old-age	2.3	5.3	5.4	8.5	9.2	9.3
Disability	5.8	7.2	6.1	8.4	8.7	8.7
Survivor	5.5	6.2	5.1	5.6	6.2	7.1

The tendency for the number of pensioners to increase relative to the number of insureds in the labor force will be with us over the next several years as well thanks to a further aging of the population and people retiring. In this sense the last wave in the growth of the number of pensioners was between 1971 and 1978, though it is the weakest in the overall survey (the annual growth rate of the number of pensioners is 3.3 percent); if we break it down, it shows that there is a continuing tendency for the number of new pensioners to increase. The average annual growth was 2.8 percent in 1975, 2.6 percent in 1976, 4.1 percent in 1977, 4.4 percent in 1978 and 4.9 percent in 1979. The new wave of pensioners is accompanied by an old phenomenon—once again the share of disability pensioners is growing more and more. It is anticipated that under the present qualifying conditions the number of pensions will increase from 1,615,000 in 1980 to 2,050,000 in 1985. The annual growth rate will in that case rise to 4.8 percent in the next wave. Since the rate of employment will be increasing between 2.5 percent and 3 percent, this will signify a further deterioration of the ratio between the number of pensions and the number of insureds in the labor force. Between 1981 and 1985 this will mean that spending for old-age and disability insurance will grow faster than the anticipated growth of the social product and the national income.

This means that the national income will have to bear the burden of new appropriations for old-age and disability insurance. The stabilization measures have, however, halted that increase. Here is why. For years the share of the national income for pensions has increased faster than the national income itself. Over the last 5 years this share climbed from 9.7 percent in 1973 to 10.1 percent in 1977 and about 10.5 percent in 1979,

which means that allocations for pensions have been increasing at an annual rate of 28 percent, while the national income has been increasing about 22 percent on the average.

The "Second" Stabilization Package

Whereas in the field of old-age and disability insurance the first stabilization package halted the faster growth of pension funds and the growth of the national income, the second has to do with halting the growth of disability pensions. The conditions for obtaining and determining the right to a disability pension are contained in the Federal Law on Basic Rights Under Old-Age and Disability Insurance. However, more detailed conditions for determination of those rights are defined by republic law. Over the last 10 years the percentage of persons receiving disability pensions has moved upward or downward as a function of the policy in the republics, without any other more evident causes.

The example of Serbia eloquently indicates the degree of correlation between the advantages offered by regulations and the relative number of disability pensions granted.

Serbia is among the regions with the highest annual growth of disability pensions and also the fastest increase in the number of new recipients of disability benefits. Nevertheless, in 1978 the new Law on Disability and Old-Age Insurance added another favorable practical opportunity for people to retire with 10 years less of work service for men and 7.5 years less for women if second-degree and third-degree disability are proven. The year after the law was adopted, the percentage of new disability pensions was 12.4 percent.

The report on operation of the Republic Old-Age and Disability Insurance Community of Serbia over the last 4 years shows that the revenues, which increased at an average rate of 24.8 percent, were altogether unable to cover the growth of expenditures (27.6 percent on the average). Except for one year the community has therefore been operating with a constant deficit. The shortage has been covered with reserves, but even they have thinned out in time, and the problematical limit has been reached beyond which the payment of pensions will be uncertain. Thus in 1973 the community could pay from its reserves the total amount for 5 months, while last year it recorded the largest drop of reserves, which at present can hardly cover pension payments for 1 month. This June it indeed happened that certain communities in Serbia were unable to pay pensions, and the pensioners waited several days for the funds to be borrowed. We must state that we are talking about the period between 1973 and 1978, when the growth rate of disability pension recipients (4.4 percent) was already higher than the growth of old-age pension recipients (3.8 percent), and slightly lower than the growth rate of recipients of survivor benefits (4.5 percent).

The strong growth of disability pensions is considerably diminishing the amount of the average pension in general and of the disability pension in particular. An analysis of pensions in Serbia in 1978 has shown a high share of pensions below the marginal amount (2,608 dinars): 43 percent of disability pensions, 52 percent of survivor pensions and 19.3 percent of old-age pensions represent pension income below that limit, and they are being received by 40,500 disability pension recipients, 40,500 survivor pension recipients and 20,800 old-age pension recipients.

In spite of these figures we should say that in recent years both the real and the nominal increase in the size of pensions has been larger than the growth of personal incomes. According to data of the Federal Committee for Labor, Health and Social Welfare Policy, between 1973 and 1978 average pensions increased at a rate of 3.8 percent in real terms, while real personal incomes increased at a rate of 3.5 percent. Pensions in Serbia recorded a similar line of growth, faster than the growth of personal incomes. Figures for last year obtained from the Federal Committee for Labor, Health and Social Welfare Policy show that the average pension has continued to rise faster than the average personal income, in fact even at a slightly accelerated rate, and this has resulted in a further improvement of the relationship between the average pension and the average personal income: from 58.9 percent in 1978 to 60.1 percent in 1979.

The principal argument for the faster growth of pensions has always been the low average pension level. The measure of indexing the increase in the size of pensions to the cost of living was adopted in order to maintain the existential minimum for pensioners.

Size of the Average Pension in Yugoslavia

Republics and Provinces	1978	1979
Bosnia-Hercegovina	2,529	3,035
Montenegro	2,965	3,665
Croatia	3,060	3,852
Macedonia	2,559	3,099
Slovenia	3,606	4,402
Serbia	3,066	3,726
Kosovo	2,228	3,135
Vojvodina	2,755	3,351

It has turned out, however, that the steady growth of funds cannot meet the needs because of the ever larger increase in the number of pensions, in which disability pensions have an ever more sizable share. Yet they, because of the shorter length of service and lower age level of insureds, are by and large low. Preservation of their size at a socially acceptable level means an additional sizable exhaustion of pension insurance funds, and the present stabilization measures must take this into account, most probably through a policy of further protection of small pensions.

What is to be done, however, to adapt the policy governing disability and old-age insurance? Probably we should begin at the beginning. That is, it has turned out that our social insurance statistics do not have even basic indicators on the composition of the insureds in the labor force with respect to age and length of service, which is the principal component of most pension systems in the world, since without it one cannot estimate the expected level of spending. Moreover, our statistics do not even have figures on the degree of disability, death rate and migration of insureds, which is a great obstacle to monitoring and studying these factors and in particular their influence on the volume and composition of expenditures in the old-age and disability insurance system. The figures on pensionable length of service, degree of disability, average and probable length of life, the mortality rate, types of activities in which insureds in the labor force work, their amount of schooling, work safety, the level of their income, family situation, and the productivity they have achieved, provide the basis for serious long-range guidance and formulation of policy concerning pension insurance. Only in late 1970 were regulations adopted on the keeping of records on insureds and pension recipients on the basis of a uniform methodology for the entire country. More complete statistical documentation, however, is expected only in the present year. Without it it is not possible to alter the policy governing old-age and disability insurance without major disruption, nor can steps of any kind be taken. Perhaps it is fortunate, then, that the drafting of the stabilization measures in this domain will coincide with the first more complete figures from records on insureds and pension recipients. The third stabilization package might therefore be drawn up more seriously and cover a longer period of time.

	1969-1973		1974-1978	
Republics and Provinces	Total Pensions	Disability Pensions	Total Pensions	Disability Pensions
Serbia	3.9	1.1	4.3	4.0

DISADVANTAGES OF IMPORTING FOREIGN TECHNOLOGY CITED

Belgrade KOMUNIST (organ of the LCY [League of Communists of Yugoslavia]) in Serbo-Croatian 15 Aug 80 p 13

[Article by Dragisa M. Pavlovic: "Tied Hands"]

[Text] Though efforts are being made to establish fairer international relations in the transfer of technology and the protection of industrial property, the present situation is still very unfavorable for our country. This situation is manifested in restrictive clauses dictated by foreign suppliers of technology in what are referred to as license agreements.

Yugoslavia has objectively been compelled to purchase patents, licenses and technological know-how. According to information supplied by the Federal Economic Chamber, up until the end of May 1972 our organizations had or were using about 500 patents, licenses and rights to know-how. They had concluded 328 contracts on industrial cooperation and long-term production collaboration with foreign partners; 52 contracts on investment of foreign capital calling for a total amount of about 5 billion dinars of joint investments; they had granted or sold 76 patents and licenses, of which about one-fifth went to the advanced countries; in their own production capacities about 50 percent of the production equipment in use had been imported from abroad.

Not many things have changed since then. Even now industry is importing most manufacturing processes. Licenses are almost the only way of obtaining technology, so long as the more complicated forms of international production collaboration are still underdeveloped and insufficiently organized.

According to the figures available, in mid-1978 there were about 600 licenses in the Yugoslav economy. An analysis of 100 contracts chosen at random shows that there are at least 5 restrictive provisions in nearly every contract.

On the basis of frequency of occurrence (about 62 percent of the cases) the most common provision is a limitation on the use of the patented innovation or "know-how" and the payment of compensation even after the life of the patent or the agreement.

In almost 44 percent of the license agreements our organizations are prevented from "researching and developing" the license which they have "obtained."

In more than a third of the agreements there is a limitation on the sale of products. In one case the agreement even has an annex consisting of a map of Yugoslavia on which a heavy line marks off the territory where our organization is "allowed" to sell the products manufactured with the license "granted," and where it is "forbidden" to do so.

Obligations Without Rights

In 31 percent of the license agreements which were examined a restriction on the business management of the "recipient" of the license is encountered, and almost the same number of agreements contain unjustified charges. One illustrative and instructive example is that of one of our organizations which concluded an agreement with a foreign firm on production of drugs and committed itself to purchasing the necessary ingredient for production at a price of 1,000 Swiss francs per kilogram solely from the "grantor" of the license. As it turned out, however, it managed to purchase that same ingredient at a tenth of the price, but from another firm. When the licensor learned about this "economic stupidity" of our organization, it was compelled to pay the "grantor" of the license 600,000 francs in cash by way of damages.

Importing licenses calls for very keen attention and caution. It is unenable to export at any price, much less import under those conditions. First of all, one should look to the needs and capabilities of his own creativity and ensure the legal foundation in license agreements for those capabilities to be brought into play. With many technologies (licenses), even the slightest change, any creative improvement, even when it is done by our workers, is regarded as the property of the seller of the technology. The owner's permission is required for any change in an innovation. In that way we become dependent on the owner of the license. That is why it is high time, now that we have several world producers for nearly every technology, that we ourselves seek out the conditions under which the work of our workers on new solutions, innovations and certain substitutions of raw materials will have definite protection.

The Purchasing of Outdated Technology

When we import technology (a license), it is important that we import something that stands at the peak of technological advance in the world at that moment.

By applying outdated technology we are "incorporating" the lag and diminishing the competitiveness of our economy on the world market. Organizations of associated labor have various reasons for deciding to adopt a technology that is not up-to-date. Sometimes it is because of lack of information, in

others because of credit financing, in still others because of the question of raw materials, and so on. Today there are still organizations of associated labor in which decisions are made on capital investment projects without professional analyses concerning raw materials, size of capacity, and the market, and without involvement of the workers in these processes through self-management. On this basis credits are nonchalantly taken at a price and for periods of time which are materially and economically unacceptable, and little or nothing is done about distribution, new organization of work, planning, and so on.

"Detailed" studies prepared with the methodology which will particularly emphasize the good aspects and conceal the bad aspects of the "undertaking" are brought before the workers for a hasty decision. Such studies will, of course, be adopted after a "good presentation." When we know that it takes us an average of 3 years to put a technology into operation, then it is clear that the optimality of any particular arrangement which we conclude falls to the lowest point very quickly.

Processing materials represent 63 percent of our imports in value terms. Machines and equipment represent one-fourth of imports, and consumer goods constitute only 12 percent. Whenever imports of machines and equipment increase, imports of materials increase in definite proportion. It turns out that with every new factory we are increasing the country's payments deficit. It is therefore important to purchase a technology which makes it possible to utilize our own raw materials. In that way we eliminate dependence for raw materials, and that means we are reducing our overall dependence on foreign countries. Every organization has a very great interest in the kind of raw materials it uses, in the kinds of reserves there are, and in the possibilities that exist for trade.

Often product markets are defined when technology is sold. It is demanded that the markets be only our country or even only parts of our country. This need not, of course, have a restrictive effect on expansion of our economy to the world market, but it could have. Market restrictions of this kind make it more difficult to carry out our policy in certain regions of the world and certain countries. We are unable to carry out certain projects; that is, we must carry them out with a partner from abroad who has sold us the license. Everyone is familiar with the case of Nikola Tesla, our well-known producer of automatic telephone switchboards under a license from the Swedish firm Erikson. The signatures on a preliminary agreement between Nikola Tesla and a customer from Algeria had not yet dried, when representatives of Erikson turned up and simply prohibited Nikola Tesla from exporting this product from Yugoslavia. They would allow it, but only through Erikson. That was what the licensing agreement said. For the enterprise Rad of Belgrade to use the BALANSI system in setting up a housing fabrication plant in Iraq, it first had to pay 10 percent of the total cost of the investment project into the treasury of that French firm.

Our organizations enter into "transactions" with foreign partners without preparations which are indispensable to successful performance of a transaction. Usually they do not have in mind all the necessary parameters for carrying out projects, and in particular analyses as to selection of technology. It is no wonder, then, that such agreements turn out to be unfavorable for our organizations of associated labor, and project completion is usually late.

In most agreements the foreign partner does not share in the risk of the joint venture. If there are service charges under the license, they are paid regardless of the profit earned. Our organizations pay a fixed amount for the technology acquired. There are cases of using the right to technology and trademark when foreign partners are paid a license fee in the form of a royalty which is a definite amount for each article manufactured or even as a certain percentage of the sales price of the product.

The importation of foreign technology has a discouraging impact on development of our research capabilities. Our organizations of associated labor have not been relying on domestic manufacturers and innovators; that is, our organizations have been reluctant to adopt domestic technology.

We dare not fall into deeper dependence in the transfer of technology. It is therefore indispensable that through purchases we safeguard the material right to a particular technology (innovations, patents and know-how), stimulate development of long-term production cooperation and develop our own capabilities for effective transfers. There is also a need to guarantee preference to domestic technological solutions when their value is equal to that of foreign ones. Likewise, we must also provide incentives for them to be transferred to other countries, especially the developing countries, through engineering, industrial cooperation and joint ventures.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

EAST-WEST ECONOMIC COOPERATION DESCRIBED

Budapest MAGYAR NEMZET in Hungarian 16 Aug 80 p 3

[Article by Dr Peter Gal: "On the Basis of Mutual Interest"]

[Text] The changes that are taking place in world economic and international political relations have a many-sided influence on international economic cooperation--particularly on one of the most sensitive areas thereof, the system of economic relations between developed capitalist and socialist countries. The continuing development of these relations requires new initiatives for which the mutual interests that might be strengthened currently and in coming years may provide a certain foundation.

Expectations and Realities

The commercial ties between European socialist and developed capitalist countries, even in the most favorable development phase in the world economy, were generally of marginal importance on the basis of trade magnitude. It accounted for only a negligible part of the economic relations of the developed capitalist countries and only about one-third of the total foreign trade of the socialist countries, but their economic and political importance far exceeded the data reflected in the figures.

In the first half of the 1970's, East-West trade increased more dynamically than world trade. Between 1971 and 1973, the exports of the developed capitalist countries to the European CEMA countries increased 18 percent and its imports from these countries increased 9 percent, both calculated in unchanged prices. Following a decline in 1974, there was again an increase in the Western imports of the CEMA countries but in exports there was a minor decline in real value. In the second half of the 1970's, both exports and imports showed a fluctuating development in real value. (At the same time, East-West trade relations at the peak of the most dynamic development in 1975 did not amount to 3 percent of world trade.)

Political changes became of particular importance against the background of mainly economic factors. The strengthening of detente, the signing of the Helsinki Concluding Document and mutual trust made the previously unfavorable

political influences more favorable. The limiting and inhibiting strength of the earlier political factor became an incentive force for a time. This change also made it possible, among other things, for the socialist countries to bridge the difference between their increased imports and exports that were rising to a lesser degree by accepting credits on the Western money markets and loans, the volume of which increased by a factor of 10 in 10 years. All these changes brought certain elements of mutual dependence into East-West relations and strengthened mutual interest in cooperation.

On one hand, the imbalance in East-West trade--the deficit of the socialist countries in their payments balance with capitalist countries and the related indebtedness--and, on the other hand, the fluctuating cyclical situation in the developed capitalist countries, and in part some political factors, resulted in modifications in East-West trade in the second half of the 1970's. In 1977, the former dynamics in East-West trade broke down: the imports of the socialist countries declined 8 percent, and their exports increased only slightly, 2 percent. But behind these figures significant structural changes are evident: while Soviet exports to the capitalist countries increased 12.5 percent, its imports from there declined 8.3 percent; at the same time, the exports of the other European CEMA countries to capitalist countries increased only 8.6 percent, while their imports from there did not decline at all but increased 3.2 percent as compared to the previous year.

The Major Partners

At the end of the 1970's, the share of the West European countries in the total exports of developed capitalist countries to socialist states was 75 percent. In 1979, the United States had a 14-percent share, while the declining Japanese share was 9 percent in the same year. To a certain extent, of course, the situation in this respect also was different between the Soviet Union and the other European CEMA countries. While the U.S. share in Soviet imports from the developed capitalist countries increased dynamically and reached 18.5 percent by 1979, the share of the Western European countries--although actually as a result of a faster growth than average--was 63 percent. (The United States and Western Europe as well increased their share at the cost of Japan.) In the other European CEMA countries, however, the West European "dominance" in imports from the OECD countries is even more important, remaining unchanged for years at 84 percent, while the U.S. share is 9.5 percent and Japan's 4.2 percent. (Let us note that the U.S. share in Hungary's total imports from developed capitalist countries is about 3 percent, which is the lowest ratio among European CEMA countries. In all European CEMA countries, the FRG has the greatest share of capitalist imports; in the case of the Soviet Union, there is a rapid growth in this ratio while in the case of the other countries there is no change. The FRG share in total capitalist imports by the Soviet Union is one-fifth, while in the "small" CEMA countries it is one-fourth.

Almost half of the total imports of the European CEMA countries from the developed capitalist countries went to the Soviet Union in the second half of the 1970's. (Poland, for example, imported 16-17 percent and Hungary 8-9 percent of the total European CEMA countries' imports from all OECD countries.)

The West European states are the best markets for the exports of European CEMA countries directed toward developed capaitalist countries. These states imported about 86 percent of the commodities of the socialist countries, from which it can be deduced that the developed, overseas capitalist countries--that is, primarily Japan and the United States--on the average covered their exports to the socialist states with fewer imports than the old world Western countries. Within total OECD imports the FRG share is the highest in imports (as is the case with exports) from the socialist countries: on the average this share was 22 percent in the second half of the 1970's. FRG firms bought about 19-20 percent of the Soviet Union's total Western exports and about one-fourth of the exports of the other European CEMA countries.

Soviet products made up 52-53 percent of exports from the European CEMA to the developed capitalist countries, whereas Polish goods made up 16-17 percent and Hungarian goods 7 percent at the end of the 1970's.

A Slowly Changing Commodity Structure

The most problematic area in the development of commercial relations between the European socialist and the developed capitalist countries is perhaps latent in the structure of the trade between the two groups. The deficit that developed during the 1970's in the payments balance of the socialist countries and together with this the increase in their indebtedness to the capitalist countries is only one of the important phenomena in trade between the two blocs. Another important manifestation of this asymmetry, which defines the first to a certain extent, is that in the exports, on one side, there are highly processed finished goods for the most part, while, on the other side, unprocessed, or slightly processed, goods dominate.

But the problem is more complicated than this. In both the socialist imports from capitalist countries and exports as well, certain favorable changes have occurred during the development thus far. The exports of socialist countries to the developed capitalist countries also show some improvement, but at the same time the structure of capitalist imports by the European CEMA countries is in part unfavorable, for the ratio of machinery, equipment and investment goods in general representing developed technology and regarded as the main goal of imports from the capitalist countries is still relatively low even after the favorable trend of the changes that have occurred in the past decades.

As for the structure of imports by the European CEMA countries from the developed capitalist countries, the most important products from the viewpoint of technical development--machinery, equipment and transportation means--had a 38-percent share by the end of the 1970's as compared to 32 percent in 1973. At the same time, the share of foods in capitalist imports in the European CEMA countries is very high--ranging from 12-17 percent. Likewise, a relatively high share, about 6-8 percent, is represented by raw materials, and at least a one-third or two-fifth share by various semiprocessed products.

Undoubtedly, the neuralgic point in the structure of East-West trade relations has been and remains in the structure of the exports by the socialist countries. Not only is the ratio of finished products exported by the European CEMA to the developed capitalist countries--primarily machinery, equipment and transportation means--low and well below the share occupied in total exports, but the growth rate as well has hardly exceeded the growth dynamics of exports to developed capitalist countries. Even at the end of the 1970's, the commodity category of machinery, equipment and transportation means made up only 8-9 percent of capitalist exports by European CEMA countries (in total exports this ratio is over 35 percent) while raw materials and fuels made up more than half of exports. The latter is even more dominating in Soviet exports, 70 percent, while it makes up, on the average, only one-fourth of the share of the other European CEMA countries. In the case of the latter, the share of investment goods is also more important in their capitalist exports, and likewise the share of consumer industrial goods is also high, about 15 percent.

Even by way of allusion, it is also worthwhile in this connection to mention the favorable effects of Western production cooperation projects. The structure of these relations is substantially more positive for the socialist countries than in case of trade as a whole. This is, of course, natural by their character. And still we should mention that while in the 1970's the share of cooperation projects in East-West trade as a whole was only 2-3 percent, almost 10 percent of the machine trade was conducted in the framework of production cooperation projects.

SED PLENUM DISCUSSION OF ECONOMIC MEASURES PUBLISHED

West German Commentary

Frankfurt/Main FRANKFURTER ALLGEMEINE in German 24 May 80 p 14

[Article signed "Gz" datelined Berlin, 23 May: "The SED Intends To Take Action Against Waste and Shoddy Work--Stricter Party Control over Cost Announced; Politburo Report." Excerpts from the SED Politburo Report follow this article]

[Text] In the present phase of organizational preparation for the next five-year plan (1981 to 1985), the SED intends to increase its efforts to check the steady cost increase in the industrial combines and in this connection to intensify party control. This was learned from the report of the Politburo to the SED Central Committee, which Inge Lange--the Central Committee member in charge of women's problems--delivered before the 12th plenary session of the Central Committee.

According to the Politburo report, parts of which were published, the development of production during the first few months of this year was by and large satisfactory and the population was amply provided with basic foodstuffs, necessities of life, children's articles and the "countless little things"; the supply of clothing was sufficient, and further progress was made in regard to high-grade technical consumer goods and other durable industrial products, "but this was not always sufficient for meeting the steadily rising demand."

According to the report, the Politburo had adopted a new resolution, which specified for each combine what kinds and quantities of consumer goods were to be produced and at what time they were to be incorporated in the production process. The report pointed out that the necessity day after day to safeguard supplies was a difficult requirement which "must be met more satisfactorily" in the bezirks and kreises [GDR administrative units].

Mrs Lange stated that the work concerning cost control, a crucial criterion, should be significantly improved. According to Mrs Lange, the targeting, recording and control of the costs in combines and enterprises and at

construction sites and the precise accounting and analysis of the costs by the directors must be organized more rigorously; the party organizations in the enterprises should intensify their efforts to insure that the struggle for maximum material and energy economies, for cost reduction and against any waste of national wealth "be waged energetically."

According to the plans, the accomplishment of these tasks is to be facilitated through introduction of new combinations of intra-plant "plan targets" that are to force the industrial enterprises to economize on materials. At the same time, the Politburo issued new guidelines that are to make possible accurate productivity comparisons between the enterprises of the industrial sector and those of the building trade. The Politburo report also disclosed that at the beginning of this year nearly 20,000 investment projects had been reviewed and that subsequently new priorities had been established, which--the report urged--should now be observed.

The report states that in the agricultural sector, where the SED has been registering, even in the recent past, "stagnation" in regard to yield--for which reason the struggle against shoddy work in the enterprises has of late been intensified by means of picture-stories in the technical journals and identification of the individuals involved--it will be necessary to concentrate all energies on "gradually overcoming" the differences in performance between the cooperatives and the enterprises.

Politburo Report by Lange

East Berlin NEUES DEUTSCHLAND in German 22 May 80 pp 4-7

[Report to 12th SED Central Committee Plenum, held 21-22 May 1980, by Inge Lange, Politburo candidate and secretary, SED Central Committee: "From the Report of the Politburo to the 12th SED Central Committee Plenum." For further excerpts from the Politburo Report which, together with the excerpts published below, constitute the entire text of the NEUES DEUTSCHLAND report, see FBIS DAILY REPORT: EASTERN EUROPE 28 May 1980 Vol II No 104 pp E 1-E 8]

[Excerpts] Having from the outset applied the teachings of Marx, Engels and Lenin to the concrete national and historical conditions of our country, we are consistently implementing the universal laws of the socialist revolution and of socialist development. The comprehensive theoretical-ideological work that was done on the occasion of the 110th anniversary of the birth of Vladimir Il'ich Lenin in appreciation of his life and work convincingly demonstrated the truth, universal validity, vitality and topicality of our world view. It again showed that Marxism-Leninism is the only true beacon toward a future of the nations free from exploitation and subjugation, the reliable signpost in the struggle for socialism, peace and human progress.

This characterized also the celebration in the GDR of the 35th anniversary of the liberation from Hitler fascism. In the life of the people, this celebration turned out to be a convincing manifestation of the indestructible fraternal friendship and cooperation with the Soviet Union. In word and deed, our citizens demonstrated that they will never forget the immense sacrifices, which the Soviet people made in crushing the barbarism of the Hitler regime, and that the German-Soviet friendship and the fraternal alliance with the country of Lenin are the solid foundation of our further progress in the development of the advanced socialist society.

The mass demonstrations that took place on the occasion of the anniversaries of liberation in the national memorials of Buchenwald, Sachsenhausen and Ravensbrueck and of the Brandenburg-Goerden penitentiary testified to the bitter and bloody struggle which German communists and other German antifascist resistance fighters--fighting side by side with their comrades from all countries of Europe--waged during the years of fascism. The words of Erich Honecker--spoken at the powerful memorial demonstration at Marienberg, Brandenburg--met with great response on the part of the people of our country: "In the German Democratic Republic, in the first workers' and farmers' state on German soil, in our socialist fatherland, our people has found its true home. Here the legacy of antifascism is being implemented and along with us all nations that are truly concerned with peace can be sure that on German soil there exists a state in which fascism was eradicated and which will never start a war."

In 2 days, the Fifth Festival of Friendship between the youth of the USSR and the young people of the GDR will begin in Karl-Marx-Stadt. Through this festival, the Free German Youth, the helper and fighting reserve of our Party, honors the 35th anniversary of the liberation, the 110th anniversary of the birth of V. I. Lenin and the 25th anniversary of the establishment of the Warsaw Pact. We are convinced that the Fifth Festival of Friendship will demonstrate anew that on the basis of the revolutionary ideas of Marxism-Leninism the Free German Youth and the Communist Youth League will remain closely allied forever.

Toward Successful Accomplishment of the Economic Tasks

Dear comrades!
In keeping with the guidelines provided by comrade Erich Honecker at the 11th session and at the discussion with the first secretaries of the kreis [GDR administrative unit] administrations, during the period under review the activity of the Politburo and of the Central Committee secretariat was oriented toward obtaining better economic results, in order to be able to prepare the 10th Party Congress and consistently to implement the resolutions of the Ninth Party Congress, which are aimed at improving the well-being of the people and at the consolidation of socialism.

In accordance with the measures adopted by the Central Committee secretariat, the work required to accomplish this focused on the following basic tasks:

Firstly: All-round fulfillment and systematic overfulfillment of the economic plan for 1980 and implementation of the objectives set by the Ninth Party Congress for the 1976/80 five-year plan.

Secondly: Further elaboration of the principal policies aimed at modernizing the structure of our country's material/technological basis and of the basic conception concerning the expansion of our national economy during the period from 1981 to 1985.

Thirdly: Further improvement of management, planning and economic stimulation so as to promote economic growth and improve work quality and efficiency.

The Politburo notes that along with all working people our Party has energetically set to work on the tasks stipulated. This is evidenced by the acclaim of the masses and their resolve in pursuing the goal of significant productivity increases to do their utmost overall to strengthen the GDR and to safeguard and gradually raise the standard of living attained.

The many outstanding commitments and initiatives concerning the all-round fulfillment and systematic overfulfillment of the economic plan for 1980 reflect the great political awareness and the deep trust of the working class, the cooperative farmers, the intelligentsia, the women, young people, and all workers in the successful policy pursued by our Party. They are an indication of the resolve of the working people more emphatically to direct the thrust of the socialist competition organized by the trade unions toward the improvement of work quality and efficiency.

The Politburo is pleased with the results of an exchange of experience between the Central Committee of our Party, the general directors of the combines and the Central Committee's party organizers of the industrial and construction sectors, which took place in March in Gera and which was conducted in a true communist spirit.

In a letter to the secretary general of the Central Committee, comrade Erich Honecker, the participants unanimously stated they would do their utmost to insure further implementation of the resolutions of the Ninth Party Congress and properly to prepare the 10th Party Congress through initiatives and new ideas and projects. Proceeding from this position concerning the overall consolidation of the GDR, the combines jointly committed themselves to produce M 2 billion worth of industrial goods in excess of the 1980 plan. On average, this is the equivalent of the production volume of 2 working days per combine, which for the most part is to be produced on the basis of material economy. It is with great pleasure that we can announce to the 12th session of the Central Committee that prior to the 35th anniversary of the liberation of the German people from Hitler fascism by the glorious Soviet Army, the combines succeeded--as a first stage--in producing one additional daily quota.

During the period under review, the Politburo concerned itself on a monthly basis with the fulfillment of the economic plan and it established all the provisions necessary to continue the steady and continuous development of the national economy. The Council of Ministers was entrusted with the implementation of the measures adopted.

Plan Fulfillment Ahead of the Targets

Thanks to the outstanding results produced by all workers in the socialist competition, the plan got off to a good start. Month after month, the objectives of the 1980 economic plan for the development of productivity were attained and plan fulfillment moved well ahead of the targets.

By the end of April, the fulfillment rate of the industrial production plan was 101.1 percent. As compared to the corresponding period of the preceding year, this represents a 6.2-percent production increase per working day. M 1.3 billion worth of industrial goods were produced in excess of the plan targets.

It should be noted that the number of combines and enterprises which each month--decade after decade--have been fulfilling their production plans and which are steadily moving ahead of the targets has been increasing. Of 115 combines and industrial VVB [associations of state enterprises], 108 fulfilled or overfulfilled the industrial production plan. The combines are becoming a great social force; they represent a stable support of our socialist planned economy.

Of great significance in regard to improved performance is the fact that the qualitative factors are assuming increasing importance. This is reflected in the fact that by the end of April, the fulfillment rate of the net production plan for centrally controlled industry was 104.8 percent. This is attributable primarily to the great efforts made by the workers in regard to reduction of industrial input and improvement of material economy.

In this connection, the Politburo plans to eliminate the still existing differences in performance and in the development of the qualitative factors involved in economic growth and to insure that every combine fully discharges its economic responsibility. It is necessary to evaluate the work of all combines by the same economic criteria. In accordance with a resolution adopted by the Politburo, a uniform evaluation standard was developed for the economic comparison of the combines' economic level and their improvements in productivity.

As compared to the preceding year, labor productivity in industry increased by 5.9 percent. In 34 combines, labor productivity increased more rapidly than commodity output.

The results produced by science and technology were the crucial factor determining the increase in productivity and the improvement of efficiency and product quality. During the period under review, 1,483 scientific-technological projects of the state plan and of the enterprises' intra-plant plans were introduced in the production process.

By the end of April, the fulfillment rate of the construction output plan was 100.3 percent. As in industry, progress has been made in the construction sector in regard to utilization of the qualitative production factors. Thus the fulfillment rate of the construction sector's net production plan amounts to 102.6 percent.

In the transport sector, the volume of goods shipped exceeded by 41 million tons that of the corresponding period of the preceding year, i.e. a productivity increase of 13.2 percent. Thus we were able better to meet the transport requirements of the national economy.

The material-technological basis of our national economy was systematically consolidated. By the end of April, the volume of investments in industry, in the construction and transport sectors and in the postal and telecommunications sector totaled M 8.9 billion, i.e. an increase of 7.2 percent.

We are consistently pursuing the course laid down for the benefit of the people by the resolutions of the Ninth Party Congress and we are systematically implementing the housing construction program, the nucleus of our social policy. By the end of April, all of the targets set by the complex housing construction plan were attained; 47,359 apartments, including 32,801 new housing units, were delivered and 2,780 openings in kindergartens and 2,242 places in day-care centers were made available.

In all bezirks and kreises [GDR administrative units], it is necessary to make available the consumer goods and services planned on a regular basis and on a high qualitative level and more significantly to improve the input-output ratio. By means of efficient construction methods, we must make effective use of the existing possibilities regarding significant overfulfillment of the targets set for housing construction or modernization in the five-year plan for the period from 1976 to 1980.

To give Berlin, our capital city, a dignified appearance is and remains a fundamental concern. Thanks to the achievements of the construction workers and their cooperation partners from all parts of the republic, the work is progressing well. In this respect, the "FDJ [Free German Youth] Berlin Initiative", the greatest central youth project in the history of our youth league, is assuming increasing importance. The volume of the construction projects accomplished in the capital since 1976 equals the architectural volume of the city of Erfurt.

Proceeding from a thorough analysis of the results achieved, the Politburo approved measures concerning the further implementation of the resolutions

of the ninth SED Congress in regard to investments and construction in the GDR capital. Thus there are clear and long-term guidelines for the development and above all for the necessary performance increase in the Berlin construction sector and for the future employment of the construction capacities of the bezirks and of the centrally controlled construction combines. This resolution insures implementation of our Party's Berlin Program without any curtailment in regard to its objectives, but with significantly improved efficiency and quality. This means that the progress made in regard to construction work in our country must be reflected above all in the construction work in our capital.

More High-Grade Consumer Goods

Mindful of the importance of a sufficient supply of consumer goods in regard to the further implementation of our policy of full employment, national affluence, growth and stability, the Politburo and the Central Committee secretariat repeatedly concern themselves with solving the problems concerning the further development of our consumer goods production.

In the first 4 months of this year, the population was amply supplied with basic foodstuffs and the necessities of life, with children's articles and with the countless little things. At the beginning of the spring-early summer season--and for the requirements in connection with the preparations for the youth consecration--a sufficient supply of clothing was available.

In regard to high-grade technical consumer goods and other durable industrial products, we made further progress, without being able always to meet the growing demand. The 11th Central Committee session stipulated that a much greater quantity of high-grade, well-designed consumer goods be produced. The Politburo has meanwhile adopted a corresponding resolution laying down the concrete tasks of the industrial ministries and of the combines. This resolution specifies for each combine what kinds and quantities of consumer goods will be produced and at what time they are to be introduced in the production process; in each case, the quotas established are minimum targets.

The Politburo again stressed the responsibility of all combines and bezirk economic councils for the production of modern consumer goods in high demand. The Politburo urged the Party's bezirk and kreis administrations and the party organizations in the combines and enterprises to intensify party control in this respect.

Reliably to safeguard supplies on a daily basis is a difficult requirement, which must be met more satisfactorily, especially in the bezirks and kreises, since the basic supplies are largely dependent on regional conditions and local production and on the quality of the work of the trade establishments. A satisfactory supply situation presupposes high-quality goods and an appropriate commodity supply by the trade sector. In this respect, the staff members of the trade collectives have set for themselves ambitious goals in the socialist competition.

The Central Committee secretariat discussed data supplied by the Council of Ministers and the federal executive board of the FDGB [Free German Trade Union Federation] in regard to the successful implementation of the pension raise, which came into effect in December of last year. Since that time, over 3 million pensioners have been receiving higher pensions. The average raise amounts to more than M 40 per month. After the measures taken in 1972, 1973 and 1976, this was the fourth extensive raise of pensions and social services that was implemented in the last decade thanks to the outstanding achievements of the working people.

Thus, our society's expenditures on pensions increased from M 9.7 billion in 1970 to M 15.3 billion in 1979. In 1980, they will amount to approximately M 16.8 billion.

The stipulation that women with five or more children, who in spite of this burden were gainfully employed for 12 years, receive a minimum pension of M 340 met with especially positive response. This regulation applies to approximately 120,000 women.

High Rate of Development in Science and Technology

Dear comrades!
We have established the basic conditions that will enable us in 1980 to take further energetic steps toward improving the material-technological basis of the national economy. The strategic work concering the development of long-term growth factors is not a matter of simply preserving the present level of the productive forces. Rather, the objective is to make use of all the possibilities deriving from the combination of the advantages of our socialist society with the scientific-technological revolution.

Proceeding from this position, the Politburo discussed the economic results produced in 1979 in research and technological development and the conclusions to be drawn from them.

It was noted that due to the significant scientific-technological results produced in many fields, it was possible to lay the foundations for greater accomplishments. The exhibits of our combines and enterprises at the Leipzig Spring Fair represent striking evidence of this. The achievements in the field of microelectronics are especially noteworthy.

As was confirmed by the exchange of experience in Gera, a measure that has proved effective in many combines was the systematic orientation of the scientific-technological capacities toward top-level performance. This approach has yielded good results.

The Politburo urges the state directors and the party organizations on the basis of thorough analyses to eliminate the differences in the levels of creative work in science and technology and everywhere to make use of the experience gained by leading combines.

As is well known, scientific-technological achievements are the principal reserve in regard to insuring significant improvements in the refinement of the available raw materials and the high level of quality of the finished products that is necessary to safeguard their competitiveness in the international markets. In this regard, greater efforts are required on the part of the chemical and metallurgical industries in regard to the development of highly refined products and on the part of all combines in regard to the production of high-grade technical consumer goods.

The Party stressed the necessity of extending the range of the economic applicability of scientific-technological results so as to make greater headway in production rationalization and in the reduction of production input. In particular, this applies to the speedy and extensive introduction of modern technologies and procedures for the reduction of working time and labor and for effecting significant material and energy economies.

At the beginning of this year, the Party discussed and approved a report of the GDR Academy of Sciences and of the Ministry for University and Technical School Affairs on the "present state of implementation of the plan concerning the long-term development of basic research, the specification of the research programs and principal lines of research and on positions concerning important developments in scientific-technological research." The strategic orientation of basic research adopted so far has proved successful and is systematically being continued. In this respect, the Party adopted resolutions concerning the further improvement of the conditions prerequisite to scientific research.

These resolutions aim further to develop and better to utilize the creative faculties of the scientists and research collectives, more systematically to direct the inquiries toward basic scientific problems and to concentrate the research work on crucial fields such as energy, raw materials, materials, microelectronics, production technology, nutrition and maintenance of health. An important task is the further intensification of the cooperation between the Academy and university researchers and the research and development centers of the combines so as to be able more quickly and efficiently to utilize research findings conducive to top-level results in industry and other sectors in regard to products, processes, technologies and methods.

The requirements in regard to the rate and effectiveness of scientific-technological progress necessitate above all creative work on the part of the scientists, engineers and innovators. Consequently, we are attributing great importance to the diverse initiatives which have been advanced by the members of the Chamber of Technology and through which they have been contributing to the speedy utilization of microelectronics and other time-, material- and energy-saving technologies.

Toward Effectiveness of Investments

During the period under review, a great deal of work was done to make the investments meet the requirements of the objectively necessary rationalization drive.

At the beginning of this year, the technical-economic indices of nearly 20,000 investment projects were reviewed in accordance with the new higher standards set by the Joint Resolution, which was adopted in October 1979 by the Politburo of the SED Central Committee and the GDR Council of Ministers and which is concerned with improving the effectiveness of investments with the object of further consolidating the productive capacity of the GDR economy.

The objective was to make appreciable progress in regard to the high-priority use of the investment funds for quick application of scientific-technological findings and to insure significant extension of the production range of new commodities.

At present, it is necessary consistently to observe the investment sequence established by the plan, the input targets approved and the start-up target dates and to exceed the technical-economic performance parameters.

The struggle for improvement of investment effectiveness includes thorough preparation of the start-up of material production projects and of the projects concerning housing construction, public education, social and cultural services and health care. For it is only through highly efficient and stable production and efficient utilization of the capacities for the improvement of living conditions that the investments serve their social purpose.

The Politburo and the Central Committee secretariat have been focusing their attention on the improvement of investment management and planning. Through the resolution concerning the decree on the implementation of investments, a new legal foundation was established in regard to the management of investment implementation. The resolution serves to increase the rights and obligations of the plant managers and combine directors and also increases their personal responsibility for the implementation of their investments.

The work collectives in the enterprises and combines of the metalworking industry have been further intensifying their efforts toward systematic utilization of the latest scientific findings in microelectronics, electronic computing and control, industrial robot technology and automation. Today the large-scale application of these findings in the production process is an indispensable prerequisite for improved product quality and reliability, for increased productivity of machines and equipment and for maximum material, energy and working time economy.

In regard to the material-technological safeguarding of the strong rationalization drive, the production of machine tools and processing machinery is of crucial importance, especially for the economical application of microelectronics and for the efficient support of the domestic production of means of rationalization. Proceeding from this situation, the Politburo in April adopted measures aimed at effecting above-average performance improvements in machine tool building, thus creating favorable conditions for the further consolidation of our material-technological basis and for the growing requirements in the export sector.

Preparations in Progress for the Seventh Construction Conference

The Politburo resolved to stage the Seventh Construction Conference of the SED Central Committee and the GDR Council of Ministers on 19 and 20 June 1980 in Berlin, the GDR capital. This conference will establish clear guidelines for insuring--through acceleration of the scientific-technological advances, intensified industrialization of construction, and consistent rationalization--increasingly efficient utilization of the qualitative growth factors in the construction sector, while simultaneously improving the working and living conditions of the construction workers.

At the same time, the conference must work out--on the basis of the results achieved so far and the construction targets set by the 1981/85 five-year plan--ways of further expanding the productive capacities of the construction sector in accordance with the growing requirements. In this regard, the further utilization of the existing architectural substance through the safeguarding of the unity of new construction, reconstruction, modernization and maintenance, a good architectural and urban design of the construction projects--a design harmoniously combining the old and the new--and energy-efficient construction are assuming increasing importance.

In connection with the work concerning the basic conception for the development of the national economy during the period from 1981 to 1985, the Politburo approved a complex proposal concerning the implementation of the housing construction program. The resolution aims to effect--by means of improved efficiency resulting from a favorable relation between new construction, modernization and maintenance of apartments--further basic improvements in the living conditions.

Thus we are establishing the conditions necessary for solving by 1990 the housing problem in the GDR as a social problem. The plans provide for an above-average development of housing construction in the capital and in the Leipzig, Dresden, Halle and Karl-Marx-Stadt bezirks.

Through systematic preparation of complex housing construction and by dynamically improving the performance of all combines and enterprises participating in housing construction through comprehensive rationalization by means of the available financial and material resources, we must insure maximum sociopolitical efficiency.

In order strictly to observe and stay below the state input norms, it is necessary above all to make more efficient use of the land and resources available for construction and to accelerate the scientific-technological advances, especially in regard to energy-efficient construction.

The bezirk administrations of our Party should now intensify their efforts toward systematic preparation of housing construction in the 1980's. Past experience shows that it is in this area that the greatest reserves can be tapped for the struggle for improved quality and efficiency. This was confirmed by the review--conducted in accordance with the standards set by the 11th Central Committee session--of housing construction plans for 206 residential areas, as a result of which it was possible--through more efficient utilization of building land and discontinuance of the demolition of buildings worth modernizing--to realize great savings of investment capital. All participants must closely cooperate to insure that in terms of city planning, architectural design and functionality the residential areas meet the qualitative requirements. We must also concern ourselves with the community service facilities and with the education of the children in the residential areas.

At the same time, the methodical preparation of the housing construction sites, including the timely development of municipal services, as an indispensable precondition for an improved construction work flow based on synchronized and continuous operation imposes heavy demands on the energy and water management and on the transport sector.

To maintain present buildings, it is planned to increase during the period from 1981 to 1985 the volume of building repair work to 125 percent, as compared to the current five-year plan period. Special efforts will be necessary to improve the performance of the building repair and janitorial enterprises, especially in regard to maintenance in urban residential areas.

We are convinced that through energetic participation in the "Beautify Our Cities and Communities--Take Part!" competition, the citizens will continue to contribute to the improvement of their living conditions.

Economical Use of Energy and Raw Materials

During the period under review, extensive work was done for the efficient development and utilization of our country's energy base so as to eliminate in all social areas any waste of energy and to replace high-grade imported energy sources by brown coal.

In view of the necessity to insure energy economy and maximum efficiency in energy consumption, new demands are being made on the planning, targeting, distribution and control of energy consumption. The Central Committee secretariat stipulated the necessary measures in this regard. Since the beginning of April, energy sources have been apportioned--on the basis of the combines' full responsibility--in the industrial, construction and transport sectors and in agriculture.

In our planning concerning the development of our own raw materials and the economical use of all available resources, the extended collection and use of secondary raw materials is assuming increasing importance. The present increase in the purchase prices of selected secondary raw materials from private households is one of the measures taken in this regard. It is planned in this way to collect and make available to industry 16,000 tons of waste paper, 28 million bottles and 22 million glasses in excess of the plan targets.

Problems Concerning Our Foreign Trade

During the period under review, the Politburo constantly concerned itself with the tasks in the field of foreign trade. Of great importance in this regard was the preparation and implementation of the Leipzig Spring Fair. The fair impressively demonstrated the growing productive capacity of our national economy and the significant foreign trade capacities of the GDR. The talks conducted during the fair by the secretary general of our Party, comrade Erich Honecker, and other leading party and state representatives produced a strong effect in the international arena and served to promote trade.

The establishment of party control over the observance of a high degree of discipline and the proper implementation of the agreed-upon shipments in connection with the measures concerning socialist economic integration is one of the measures that have proved effective in regard to the systematic development of the socialist economic integration with the USSR and the other CEMA countries. A resolution to this effect was adopted for the 1980 plan by the Central Committee secretariat and transmitted to the bezirk administrations. This resolution focuses on the implementation of the tasks in connection with the program for production specialization and cooperation between the GDR and the USSR which was signed on the occasion of the 30th anniversary of our republic. Thus party control greatly helps to consolidate the basis of our national economy and to promote the economy's further dynamic development.

The strategy for our economic development in the 1980's entails higher demands on the central state management and planning of the economic reproduction process and on the further consolidation of democratic centralism. The key problem is better to reconcile the basic economic requirements concerning increased performance and marked reduction of input with the economic interests of the combines and enterprises.

Performance-Promoting Indices

In view of this situation, the Politburo adopted during the period under review a number of basic resolutions intended more emphatically to improve the performance and the work quality and efficiency of the combines and enterprises in industry and in the construction sector:

It was resolved to use--beginning in March--indexes for industrial commodity output, net output and basic material expenditures per M 100 of commodity output in the management, planning and accounting of the combines and enterprises and of the economy as a whole. This helps to implement the principle: What benefits the national economy is bound to be beneficial for the combines and enterprises as well.

Closely interrelated, these three indexes have a performance-promoting effect. In the light of these and other qualitative criteria of performance evaluation--such as improvement of labor productivity, cost reduction, share of products bearing the "Q" quality seal--it is becoming more apparent to what extent the increase in the productivity of the combines and enterprises is a result of the utilization of the qualitative production factors. At the same time, the enterprises' own contribution to the augmentation of the national income and to the reduction of production input is evaluated more realistically.

Thus the workers' initiatives concerning the reduction of production input are supported still more effectively and taken into account in the performance evaluation. The raw material, material and energy economies lead to higher profits and at the same time to increasing net output. The index for basic material costs per M 100 of commodity output serves to orient the workers toward more effective material economy and toward a high level of product refinement.

It is now necessary to make use of the possibilities of uniform evaluation, which have been created by this Politburo resolution on all levels of industrial and construction management, for accurate performance comparisons so as to overcome the as yet considerable differences in performance development and further to improve work quality and efficiency for the benefit of the people and of each individual worker.

The Politburo also adopted special measures for improving performance evaluation in the construction sector. These measures aim above all more extensively to orient the management, planning and evaluation of the projects toward the requirements concerning a high level of construction efficiency and quality and toward significant reduction of construction costs, material input and working time. These measures serve to focus the creative initiative of the collectives in the construction combines and enterprises on completing the investment projects planned by the target date specified and in accordance with the qualitative and contractual terms stipulated.

The resolution aims to generalize the experience gained in regard to motivating the planners for elaborating efficient, material- and energy-saving project solutions. According to the stipulations, attempts will be made this year in a number of construction industry combines and in enterprises of the bezirk- and kreis-controlled construction industry to carry out the planning, accounting and complex evaluation of the work on the basis of the

following indices: completion of the planned utility projects within the limits of the input targets established, development of construction output and net output, and reduction of costs. In connection with the performance evaluation, the new construction work prices that came into effect in 1980 must be extensively used for an effective reduction of construction, material and energy input and for the improvement of product quality and productivity.

The Politburo emphasizes that the work concerning cost control--a crucial criterion for the effectiveness of intensification on all management levels--must be markedly improved. The directors must strictly organize the targeting, recording and control of the costs in the combines and enterprises and at the construction sites and they must insure accurate cost accounting and analysis. The party organization in the combines, enterprises and at the construction sites should intensify their efforts to insure that the struggle for maximum material and energy economy, for cost reduction and against any waste of national wealth is energetically waged everywhere.

Results and Tasks of Socialist Agriculture

Dear comrades!
Among the cooperative farmers and all other workers in agriculture and forestry and in the food industry, the 11th Central Committee session and the speech of comrade Erich Honecker before the first kreis secretaries gave rise to diverse new initiatives concerning the steady provision of the population with foodstuffs and of industry with raw materials. Commitments to contribute through outstanding results in the socialist competition to the proper preparation of the 10th Party Congress are striking evidence of their acclaim.

In the first 4 months, the cooperative farmers and the workers in agriculture and forestry and in the food industry met the plan targets for 1980. As of 30 April, the fulfillment rate of the plan targets for meat animals was 101.3 percent, for milk, 102.0 percent and for eggs, 107.9 percent.

In the LPG [agricultural producer cooperatives] and VEG [state farms], the collectives are continuing their efforts to provide a solid foundation for the production of meat, milk and eggs by maintaining large and stable supplies of livestock. As regards cattle (5.6 million head) and hogs (11.9 million head), the present herds are the hitherto largest. Greater efforts are necessary to insure systematic reproduction of dairy cattle. All livestock breeders must devote special attention to the improvement of their breeding results.

On the basis of the stock on hand and of the progress made in regard to control of supplies, the population was systematically provided with potatoes, vegetables and fruit. As regards hothouse-grown vegetables, the production volume totaled 13,779 tons.

Efficient Utilization of the Soil and of the Other Resources

In order partially to offset the feed deficit, the Politburo and the Council of Ministers adopted appropriate measures aimed at supporting the cooperative farmers and workers in the LPG and VEG. The workers of the state forestry enterprises have regularly been meeting the plan targets for lumber and fiberboard.

Proceeding from the 11th Central Committee session, the Politburo in January examined in detail the problems in agriculture, forestry and in the food industry and passed significant resolutions regarding the tapping in 1980 of additional reserves for increasing production and reducing production input so as to improve the input-output ratio in agriculture. At the same time, the Politburo established principles concerning the work of the cooperation councils in socialist agriculture as well as the tasks and mode of operation of the kreis Council for Agricultural and Food Management.

These resolutions and their consistent implementation were discussed at the seminars that were conducted in February in all kreises with the party secretaries, chairmen and directors of the LPG and VEG and their cooperation partners. The talks held at these seminars showed the great sense of political responsibility and the readiness of the leading cadres of the LPG, VEG and other enterprises in collaboration with their collectives to do their utmost to obtain better results in livestock breeding and crop cultivation by means of a more efficient utilization of the soil and all other resources.

The bezirk and kreis administrations of the Party established the conditions necessary for conducting these seminars on a high political level, and on their part the administrations showed a great deal of active involvement.

It is largely due to the administrations' increased support of the basic party organizations in the LPG and other socialist agricultural enterprises that the basic problems of political and economic development are discussed with increasing political intensity at the general meetings, especially the annual meetings, and that efforts are being made to take firm positions in the struggle to set high production targets. The LPG plenary assemblies underscore the increased socialist awareness of the cooperative farmers.

The experience generalized in the Politburo resolutions and the principles established in regard to the work of the cooperation councils and in regard to the tasks and mode of operation of the Agricultural and Food Management Council have been fully approved by the cooperative farmers and workers in the LPG, GPG, VEG and other enterprises of socialist agriculture. Unanimously, they regard these resolutions as important steps toward further enhancement of the responsibility of the cooperative farmers' class and toward consolidation of cooperative ownership.

With the implementation of these resolutions, further progress will be made in the all-round deepening of cooperative democracy and in the development of the cooperative farmers' and workers' responsibility for the management and planning in the cooperatives and enterprises and the cooperation among them and for the development in the kreis. This has been demonstrated by the general meetings of the basic party organizations, by the annual meetings of the LPG and by the meetings of the cooperation councils.

Further Increase Output and Performance

At these meetings, the cooperative members have been discussing ways of insuring--through increased democratic cooperation--that organizations established by them--such as inter-plant construction organizations, soil improvement cooperatives and agrochemical centers--are more emphatically brought into action for the concerns of agricultural production in the cooperatives and for the requirements in the villages. The Central Committee expects the state organs fully to adhere to the guidelines established in this regard.

Further progress has been made in regard to the intensification of cooperation. In accordance with the principles adopted, the cooperation councils were granted greater authority for the purpose of safeguarding the agricultural reproduction process in their regions, and the quality of the work done by them has been improving.

In most of the kreises, the Agricultural and Food Management Councils have taken up their work. A great many experienced and deserving cooperative farmers and workers have been called to assist the chairmen and directors. Now it is necessary systematically to continue the work in all kreises and to focus all efforts on gradually overcoming the existing unjustified differences in performance among the LPG and enterprises.

In accordance with the stipulations of the Central Committee secretariat, central discussions were held in regard to the further tasks of the agrochemical centers as inter-cooperative institutions and in regard to increasing and stabilizing the production of sugar beets and their efficient processing. Scientists as well as party secretaries, specialists and managers of the LPG, VEG and agrochemical centers participated in the discussion of the tasks in connection with the further intensification of crop cultivation. Some first results are reflected in the activities during the spring field work.

Just in time, the Central Committee secretariat passed an appropriate resolution focusing on the political-ideological and organizational preparation and implementation of the spring-time field cultivation and maintenance work. On the basis of this resolution, the work was carried out on a high qualitative level. In keeping with the stipulations of the 11th Central Committee session, the cooperative farmers and workers in the LPG and crop cultivation VEG--supported by the workers in the agrochemical centers and

kreis enterprises for agricultural technology--cultivated the entire agricultural acreage. Now it is necessary to focus all efforts on the maintenance work--one of the factors determining the yield per hectare.

Stable Links to the Trade Sector

On the basis of the conclusions drawn from the experience gained in 1979, the Central Committee secretariat concerned itself with the production, purchase, storage, processing and marketing of fruit and vegetables with the object of better meeting consumer demand.

Above all, the fruit and vegetable growers and the comrades in the processing and retail trade sectors have been urged to insure production of a broad assortment of high-quality produce and energetically to curtail losses in all sectors. The storage and retail trade sectors must intensify their efforts so as to be able at all times to meet the consumers' demand for fruit and vegetables.

It is necessary through close cooperation between the trade organizations and the branches of the Association of Allotment Gardeners, Homesteaders and Small Livestock Breeders to improve the conditions concerning the wholesale buying of products in excess of the producers' own requirements.

At the instigation of the Central Committee secretariat, a central conference was held with the party secretaries, directors and specialists of the freshwater fishing VEB and the production cooperatives of working fishermen.

In keeping with the growing importance of freshwater fishing for the exploitation of domestic reserves, the conference discussed measures concerning the intensive utilization of all available waters. Through utilization of the advances made in science and technology, through rationalization measures and reconstruction of the available waters and installations, the freshwater fishing industry must improve the input-output ratio in the interest of greater productivity.

It is the responsibility of the bezirk and kreis administrations systematically to support the basic party organizations in the freshwater fishing VEB and the production cooperatives of working fishermen.

The Suhl bezirk administration reported to the Politburo on the implementation of the resolutions concerning forestry which were passed by the Ninth Party Congress. In this connection, honorable mention was made of the great accomplishments of the forestry workers in regard to safeguarding a sufficient supply of lumber. In this sector, the principal task now is further to increase the domestic lumber output, more fully to utilize it and to develop close cooperation between the state forestry enterprises and the enterprises of the woodworking industry.

Problems Concerning Science and University Affairs

Dear comrades!
During the period under review, the Politburo and the Central Committee secretariat repeatedly occupied themselves with problems concerning science and university affairs--problems deriving from these sectors' growing importance for social and scientific-technological progress in the GDR.

The Politburo resolution of 18 March 1980 on the "tasks of the universities and technical colleges in the developed socialist society" is of crucial importance for the Party's policy concerning science and university affairs. The resolution demonstrates the continuity of scientific work in teaching and research and the great responsibility of our country's foremost educational institutions for the training of scientifically highly trained cadres devoted to the cause of socialism. The resolution aims to strengthen the unity of teaching and research and of theory and practice and fully to utilize the advantages of socialism in safeguarding a high level of quality and efficiency of scientific work. The resolution serves further to consolidate the alliance between the working class and the socialist intelligentsia.

The resolution and its implementation in the party organizations and state administrations, in the science, student and work collectives has given fresh impetus to the constructive discussion of all related problems in connection with the preparation of the GDR's Fifth University Conference in September 1980.

This is evidenced by the many letters, comments and proposals issuing from a large number of scientific meetings and from conferences with the work partners and by the results of the FDJ [Free German Youth] student days and progress shows at the universities. It is justly assumed that the objectives of the resolution are oriented toward both immediate and long-range concerns.

The Politburo resolution defines the higher requirements concerning scientific work and--derived from this--the qualitatively new demands in regard to education, training and advanced training, academic studies and research. All educational institutions and scientific disciplines should discuss the most effective ways of implementing the resolution's objectives. Implementation of the resolution necessitates above all creative participation, initiative and work on the part of all university members; but it also calls for farsighted management, planning and organization of the research, study and work processes by the state organs in charge of the universities and in particular by the Ministry for University and Technical School Affairs.

The party organizations of the universities and technical schools should further increase the fighting strength of the party collectives and the effectiveness of the political-ideological work aimed at implementing this

resolution, which is in keeping with our party program's basic policy regarding the universities.

High-Quality Instruction and Education

The resolutions of the 11th Central Committee session have met with lasting response on the part of the party organizations in the national education sector. At present, all of the initiatives of the teachers and educators are oriented toward showing solid work results at the conclusion of the 1979/80 school year so as to lay a good foundation for the coming school year. In this regard, they are concentrating above all on insuring a higher qualitative level of instruction and educational work in every class, subject and lesson.

Of great importance are the intensified efforts of many industrial and agricultural enterprises, which are aimed at further improving the polytechnical instruction and increasing its impact on the communist education of the students.

The kreis administrations have effectively been supporting the schools and enterprises. Through courses of instruction for school party secretaries, leading staff members and teachers of civics, in which kreis administration secretaries and other leading functionaries participated, the teachers and educators were given valuable assistance for their political and pedagogical work.

At various meetings, the bezirk and kreis administrations continued their efforts in regard to discussion of the experience of the various educators, elucidation of problems of communist education as a task of society as a whole and control and coordination of the cooperation of all participants from the point of view of a close connection of school and life.

The Politburo analyzed the state of medical research in the GDR and at the same time approved the basic trends of its future development. Through its results, this scientific field deeply affects the physical and mental well-being of man. Thus it is only natural that the citizens entertain great hopes in regard to new, significant results in medical research.

Research for the Benefit of the Citizens

In the past 35 years, there developed in our republic an efficient health and social service sector, which through its medical services for all citizens enjoys great respect in the international arena. At present, the further general improvement of national medical care--accompanied by the continuing expansion of the personnel-related and material capacities of the health service--depends above all on qualitative factors. Medical research and training increasingly determine the further improvement of medical work and represent the focal point of the health policy pursued by our Party.

Medical research has been charged with the task of obtaining through its work vital knowledge in regard to the causes and conditions underlying disease and health and in regard to improved control over the processes of human life. In this regard, it must increasingly take into account the requirements resulting from the increased incidence of chronic diseases. It is necessary centrally to support especially those research projects, in which it is possible--with due regard for the medical traditions of our country--to establish favorable material-technological and staff-related conditions and to produce results conducive to medical progress. This has been confirmed by the individual results that have been obtained in the last few years and that have won international recognition.

The Politburo holds that the scientists engaged in medical research are capable and ready to work hard to attain these new ambitious goals.

Lively Intellectual-Cultural Activity

During the period under review, the successful development of intellectual-cultural life and of artistic creation has been continued through diverse activities. The resolutions adopted at the 11th Central Committee session oriented thought and action in all fields of cultural work toward finding ways of further improving the quality and ideological effectiveness of the cultural and artistic achievements and of more effectively guiding the cultural life in the enterprises and regions.

The Central Committee secretariat received information concerning the elections in the Writers' Association, the results of the bezirk art exhibitions, the political-ideological situation in the theatrical field and the developments in the field of entertainment.

Fully aware of their growing responsibility, the writers, artists and cultural activists are proving themselves--in word and deed--to be active participants in the struggle for peace, for the all-round consolidation of socialism and against the imperialist threat of war. This was demonstrated at the plenary session of the GDR Academy of Art, which took place on the occasion of the 30th anniversary of its establishment.

The "GDR Days of USSR Friendship and Culture" and the Second Festival of Popular Art in Socialist Countries proved to be significant events of intellectual-cultural life. Diverse events such as the National Film Festival in Karl-Marx-Stadt, the Week of the Book with over 3,000 festive events, the Leipzig Theater Workshop, the GDR Days of Music in Berlin, the entertainers' competition and the Halle bezirk Days of Popular Art at the Palace of the Republic are proof of the high qualitative level of our socialist art and culture.

The "Intergrafik" Fair and the International Leipzig Book Fair were events of international caliber. In all bezirks, professional and amateur artists are presently getting ready with new works for the 18th Rostok Workers' Festival.

Pioneering Work as Defined by Thaelmann

The Politburo received a report by the SED's Aue kreis administration on the implementation of the resolution of 24 July 1973--"For a high level of socialist education in the 'Ernst Thaelmann' pioneer organization." The report conveyed positive results and experience in regard to the communist education of the oncoming generation and confirmed that this education is based above all on active learning and work attitudes, noteworthy socially useful accomplishments and great solidarity achievements of many pioneer collectives. The Politburo instructed the party administrations, pioneer leaders, educators and helpers of the "Ernst Thaelmann" pioneer organization markedly to raise the level of the children's communist education. In this regard, the FDJ base organizations and the pioneer friendship groups bear great responsibility.

The leaders of the pioneer friendship groups are expected enthusiastically to propagate--in their capacity as FDJ functionaries--the ideals of Communism among the children. It is their responsibility in collaboration with the educators, FDJ members--especially those in the schools--parents, sponsoring enterprises and other social forces convincingly to transmit to the children the policy of the Party and the world view and ethics of the working class.

This is the principal task of the "Ernst Thaelmann" pioneer organization. With due regard for the age and the interests of the children, this political work should be carried out in all pioneer groups and it should be combined with diverse collective experience and concrete socially useful work.

Moscow Awaiting the Youth of the World

Dear comrades!
The most important sports event in the period under review were the 23rd Olympic Winter Games in Lake Placid. With their magnificent achievements and their civic bearing, our sportswomen and sportsmen were worthy representatives of our German Democratic Republic at these winter games. Together with the athletes of the 37 participating countries, they helped to strengthen the humanitarian intent of the Olympic movement, which is oriented toward peace, mutual respect, equality and friendship among the nations.

With nine Olympic victories, seven silver and seven bronze medals and numerous other good placements, these athletes were the most successful GDR team in the history of the Olympic winter games.

On the occasion of the award ceremony for deserving athletes, coaches, exercise physiologists and sport functionaries, the secretary general of the SED Central Committee and chairman of the GDR Council of State, comrade Erich Honecker, expressed his appreciation of this outstanding performance

of our Olympic team. On behalf of the party and state leadership, he paid tribute to these magnificent results, which the population welcomed with pride and joy.

The hopes of the youth of the world are now focusing on the 22nd Olympic Games, which in a few weeks will be festively opened in the Moscow Lenin Stadium. However, this anticipation is being marred by the ignominious, indefensible actions of those circles that are opposed to the Olympic games, that have long been objecting to the policy of peaceful coexistence and that want to abuse for their reactionary machinations the Olympic idea, the great athletic competition bringing the nations together.

True Home of the Olympic Idea

We should not fail to mention that in this situation the International Olympic Committee unanimously spoke up in favor of the preservation of the Olympic movement and reminded all national olympic committees of their duty to insure observance of the Olympic rules. This also applies to the fair attitude of the International Sport Federation and of the president of the Association of National Olympic Committees.

In this connection, it is characteristic that in regard to the Olympic problem the FRG--of all nations--decided against the participation of FRG athletes in the Olympic games in Moscow and that the initiators of the boycott--through their opposition to the athletes, to the Olympic idea and to detente--chose to isolate themselves. What is welcomed in the international arena is not the policy of threats and confrontation in the world of sports, but common sense and support of international athletics.

The GDR sportswomen and sportsmen will train hard for the Olympic games. Their participation in the Moscow games will again demonstrate to the whole world that the existence of the GDR--a socialist state on German soil in which the Olympic idea, which is oriented toward peace and international understanding, has found a true home--is a blessing for our people and for the world.

In our socialist society, we implement the Olympic idea through the simultaneous development of mass-participation sport and competitive sport. It is along these lines that the GDR DTSB [German Gymnastics and Sports Federation]--in collaboration with other social forces--has been intensifying its efforts to raise the level of physical exercise and sports and to make them accessible to more and more citizens.

Worth mentioning in this connection are the good results produced at the Children's and Youth Spartakiad [athletic competition] in the winter sport disciplines, which was staged in the kreises and bezirks. Over 200,000 children and juveniles participated in the preliminary competitions. The Spartakiad contests in the various sports and disciplines were conducted on a high athletic level. We can make use of this experience for promoting

still more emphatically regular athletic activity on the part of the children and juveniles.

Cooperation Based on Solid Tradition

Of great importance for the close comradely cooperation aimed at the all-round accomplishment of the new exacting tasks was the extensive exchange of information and experience that comrade Erich Honecker--following a proven tradition--engaged in immediately after the 11th Central Committee session with the chairmen of the allied parties and the president of the National Council of the National Front.

We greatly appreciate the fact that the leaders of the allied parties and the board of directors of the National Council thoroughly studied the speeches delivered by comrade Erich Honecker at the 11th Central Committee session and at the conference with the first kreis secretaries. The conclusions drawn for their own political-ideological and organizational work are a reflection of the joint work for our socialist state, in which all of the parties and mass organizations united in the democratic bloc and in the National Front are participating.

We fully approve of the activities of the National Front committees that aim to organize political talks in the residential areas, house-communities and families in accordance with the basic CC secretariat-approved policy of the National Council of the National Front in regard to continuation of the "Take Part!" competition.

Consolidation of Our Fighting Alliance

Dear comrades!
The entire Party has been working hard and successfully further to implement the resolutions of the Ninth Party Congress and to prepare the 10th Party Congress.

It is of great importance that at this stage in particular our Marxist-Leninist fighting alliance has made significant gains in fighting strength and solidarity with the masses, as a result of which we can confidently tackle the coming great tasks.

The Politburo feels that thanks to the thorough study of the materials of the 11th Central Committee session and of the speech delivered by the secretary general of the Central Committee, comrade Erich Honecker, before the first kreis administration secretaries, the Communists and the Party collectives have been oriented toward the new requirements in connection with the further development of the advanced socialist society in the GDR. They have thus been enabled to make a greater contribution to the implementation of the Party resolutions.

The workers and Party members were greatly pleased to learn of the Central Committee's resolve consistently to pursue--even under changed conditions--the political course aimed at accomplishing the principal task.

Of special importance for the speedy and uniform mobilization of our Party were the bezirk administration sessions, which were conducted on a high level. In accordance with the resolution of the Central Committee secretariat, kreis party conferences were held, which were attended by approximately 150,000 comrades. These conferences generated new ideas regarding the improvement of the quality and efficiency of the Party work.

Above all, the conferences helped more emphatically to concentrate the management work of the bezirk and kreis administrations on creating in the Party and in all workers the awareness necessary for solving the tasks of the 1980's.

Thanks to the specification of the new problems, we are able better to meet the growing demands on the leading role of the Party and to establish the necessary fighting positions in the base organizations.

Evidence of this is the further improvement of the planning work of the bezirk and kreis administrations and of many base organizations, which on the basis of informative, accurate analyses are increasing their own contribution to the further consolidation of our republic. Thus the administrations are establishing a solid starting position for the political guidance of the social processes; they are exerting influence on the elaboration of ambitious performance objectives and at the same time are insuring the large-scale participation of the workers in the proper preparation of the 10th SED Congress.

These results have been confirmed by the report of the SED's Magdeburg bezirk administration to the Central Committee Politburo on the "evaluation of the 11th SED Central Committee session and of the conference of the Central Committee secretariat with the first kreis secretaries." It is especially since the last conference of bezirk deputies that it has been possible--through systematic management work of the Magdeburg bezirk administration--to tap significant reserves for accelerating the rate of economic growth.

Proceeding from this report, the Politburo instructed all bezirk administrations to place greater emphasis on the political-ideological work among the masses, which is the corner-stone of the Party work.

Work Among the Masses Highly Effective

Experience has shown that the work among the masses is all the more effective, the more the propagation of our Marxist-Leninist world view focuses on the basic laws of social development and on the interrelationship between domestic and foreign policy. Comrade Erich Honecker's statements

in regard to the consistent combination of the advantages of socialism with the scientific-technological revolution and in regard to the effect of the performance principle and its role as a driving force of socialism are especially helpful in deepening the understanding of the dialectical interrelationship between the advance of our social system and the exacting requirements made on each of its members. Comrade Honecker's statements help to create a social atmosphere conducive to the development of productive capacities and of the will to work for the consolidation of the GDR. They impel many party and work collectives at greater length to discuss work attitudes, responsibility, honesty, discipline and the full utilization of the productive capacities in their fields, to eliminate shortcomings and energetically to oppose any instances of dawdling.

The bezirk administrations must more effectively help the kreis administrations more extensively and efficiently to discharge their responsibilities vis-a-vis the base organizations so as to enable them better to define the crucial work problems and to accomplish the exacting tasks concerning Party work and the work among the masses.

The intensified concentration on the guidance and control of the kreis administrations in the consistent implementation of the Central Committee resolutions must be more closely linked to the joint discussion of acute developmental problems and to the assistance rendered in their solution. This applies above all to the development of production and to the transmission of the most valuable experience gained in important combines and enterprises, in the construction sector, in the local supply sector and in socialist agriculture.

List of Topics for the 1980/81 Party Instruction Year

It is also in regard to the management work of the state and economic organs that the political-ideological guidance is assuming greater importance. In this regard, it is imperative that the directors at all times fully discharge their responsibility and set a personal example. Above all, it is necessary to keep the workers informed on political and economic interrelationships and on problems arising in the course of the accomplishments of tasks and to encourage criticism and self-criticism. This serves to stimulate zealful work and to increase productivity.

Comrades!
It has again and again been demonstrated that in regard to the political-ideological work the party instruction year is of great importance. Thus the Central Committee secretariat's resolution on the "list of topics for the groups and seminars in the 1980/81 party instruction year" places special emphasis on the study of the growing role of the Party and on the tasks of the basic party organizations in the preparation of the 10th Party Congress. A more thorough analysis of the laws of the global revolutionary process, of the economic laws of socialism and their conscious utilization for continuing the efforts toward accomplishment of the principal task

under changed conditions and the thorough study of the history of the SED and of the life of Ernst Thaelmann will likewise be of great benefit in this regard.

The Personal Talks Consolidated Our Ranks

Comrades!
The Central Committee members and candidates have been presented with the Politburo-approved final report on the implementation of the resolution of the 11th Central Committee session concerning the checking of Party documents and the proper registration of the Party members and candidates.

We can say that this important political-organizational measure has been fully incorporated in the party organs' management work regarding the implementation of the resolutions of the 11th Central Committee session and of the objectives established at the conference of the Central Committee secretariat and the first kreis secretaries. The Politburo appreciated above all the personal talks and the many suggestions and proposals submitted by the members and candidates. This is a reflection of the encompassing intra-party democracy and of the great willingness to accomplish the tasks confronting the Party.

The principal results of the inspection of documents can be summarized as follows:

--The further consolidation of our Party and the unity of its ranks have been impressively confirmed. The trust in the policy pursued by the Central Committee and in its secretary general, comrade Erich Honecker, is reflected everywhere. There is no doubt that our Party is closely linked with the working people.

--The political-ideological work has been given fresh impetus. It has become more offensive and more concrete. It is thus creating the awareness necessary for the further development of the advanced socialist society in the GDR and it increasingly corresponds to the intensifying class struggle with imperialism.

--The struggle for the fulfillment of the economic plan and the conscious utilization of the qualitative factors concerning the expansion of our economy's productive capacity are increasingly becoming the principal motive underlying the actions of the Party members. The fighting programs of the base organizations have proved to be a mobilizing factor in regard to the model role of the Communists and the large-scale participation of the working people in the socialist competition and in regard to the control and solution of the economic problems.

--Both intra-Party life and Party education have been greatly enriched. The Party work is more and more characterized by optimism and a constructive spirit. The base organizations' capability of creatively implementing the resolutions of the Central Committee has been growing.

In accordance with the guidelines of the SED Central Committee, personal talks were conducted with 2,113,913 comrades (i.e. 99.2 percent), and their documents and lawful registration were checked; 2,105,537 comrades (i.e. 99.6 percent) established the validity of their party documents; 8,376 party documents that for various reasons were declared invalid were seized and new ones were issued.

In checking the Party documents and the proper registration of the members and candidates, the Party accomplished a great task. The fact that hundreds of thousands of comrades are trying--with great modesty, hard work and a sense of responsibility--to accomplish tasks deserving of recognition and appreciation is evidence of the healthy and vital organism of our Party. Supported by more than 300,000 volunteer helpers, the bezirk and kreis administrations and the administrations of the base organizations conscientiously checked and complemented the registration documents.

The inspection confirmed that the present system of registration of the members and candidates--which is in accord with the guidelines for the organization work of the Party--is fully effective.

The talks focused on the creative and constructive exchange of views on the personal contribution of each comrade to the further expansion of our economy's productive capacity, on the participation in the ideological struggle of the Party and on the tasks and requirements concerning the safeguarding of peace. Characteristically, the talks were conducted in an open, comradely spirit distinguished by a pronounced sense of responsibility.

The Party administrations have come better to know the abilities of a large number of young promising Party members and are thus in a position to support them and to include them more effectively in the Party work. The talks also showed that in the future work more emphasis should be placed on Party education, on training, on the development of volunteer work, on the work in connection with Party commissions and on the encouragement of criticism and self-criticism.

The base organizations also dealt with those comrades, who in the past had not always been sufficiently conscientious in implementing the Party resolutions, in whom word and deed had not always been in agreement. Taking heed of the criticism expressed in the personal talks, these comrades again fell in with the Party collective; 3,944 comrades, who were not prepared to follow the Party regulations, who were unworthy of Party membership, withdrew from the Party.

The proposals, suggestions and criticisms submitted in the course of the inspection of documents are a veritable storehouse of ideas conducive to the improvement of the Party work and of the work in all social sectors. They reflect our intra-Party democracy and the high level of our comrades' political work.

Optimistically Preparing for the Party Congress

Thus those Party administrations acted correctly, which incorporated in their management activity the process of recording, processing and answering the proposals and criticisms and which in the general meetings in April and May reported on the state of implementation of these proposals. Now it is necessary to clarify the as yet unsettled questions and to subject this process to strict Party control.

Every administration should be aware of the fact that the accomplishment of these tasks is a matter involving the authority of the Party and the relationship between the leadership and the individual comrade. Consequently, we must not allow a single proposal, suggestion or criticism to remain unanswered.

All administrations are well advised to make use of this storehouse of experience for raising the level of leadership and for drawing general conclusions for the Party work and the work among the masses.

Comrades!
Thanks to the results produced in regard to the implementation of the resolutions of the 11th Central Committee session and of the objectives formulated in the speech of the secretary general of the SED Central Committee before the first secretaries of the SED kreis administrations and in regard to the inspection of the Party documents and the proper registration of the members and candidates, we have established good starting positions for optimistically and confidently entering the crucial phase in our preparations for the Party Congress.

Looking forward to the 10th Party Congress, we are now confronted with the task of preparing and implementing the Party elections--a significant event for our Party and our entire nation.

Frankfurt/Main FRANKFURTER ALLGEMEINE in German 24 May 80 p 2

[Article signed "Gz" datelined Berlin, 23 May: "Resistance in GDR Enterprises to the Introduction of New 'Indexes'--Party Leadership Discusses Potential for Further Improvement of Performance." The discussion speeches to the plenum by Gerhard Schuerer, Hans Modrow, and Herbert Ziegenhahn, cited below, are published following this report]

[Text] During the deliberations of the SED Central Committee, which convened on Wednesday and Thursday, several speakers criticized the considerable differences in performance in the enterprises. Certain enterprises were identified by name. Hans Modrow, first secretary of the SED's Dresden bezirk administration, said that in the enterprises "the attitude of waiting for ready-made solutions, which is still encountered in some places,

must be consistently eliminated." He pointed out that the rate of quality improvement was not sufficient. Herbert Ziegenhahn from Gera stated that through exchange of experience and performance comparisons, "reserves of new orders of magnitude" should be opened up. Similar views were expressed by the Party secretaries from the Schwerin and Rostok bezirks, which are oriented more strongly toward agrarian concerns; these secretaries emphatically pointed the need for higher yields.

An important contribution was made by the chairman of the State Planning Commission, Gerhard Schuerer, who familiarized the Central Committee members with ways of more effectively "stimulating" the workers to improve their performance. The new industrial indexes that presently are being discussed in the GDR publications are to effect cost reductions and material economies. Schuerer's statements--insofar as they have been published--also indicate that the introduction of the new indexes apparently has met with resistance in the enterprises. At any rate, Schuerer pointed out that the planned improvement of efficiency was concerned with a "cardinal problem"--a problem that affected the present five-year plan terminating at the end of this year more than the coming five-year plan--namely "to improve material refinement and to create more value, more goods and more finished products."

Since the agenda of the 10th SED Congress, which will be held in the week before Easter 1981 (11 to 16 April), has already been published, it has been learned that--as was the case at the last Party congress--the directive on the next five-year plan (1981-1985) will be submitted and confirmed by Premier Stoph. At a later date, the new five-year plan will be formally confirmed by the GDR People's Chamber. That means that in the next few months the enterprises and the planning organs will conclude the preparations for this directive, especially since the directive must be coordinated--at least in regard to its basic points--with the partners within the Council for Mutual Economic Assistance and with the Soviet Union in particular.

Schuerer Defends New Policies

East Berlin NEUES DEUTSCHLAND in German 23 May 80 p 6

[Excerpts from the discussion speech to 12th SED Plenum by Gerhard Schuerer, candidate, SED Central Committee Politburo; deputy chairman, Council of Ministers; and chairman, State Planning Commission: "Growth of Performance and Efficiency Will Be Stimulated"]

[Text] Dear comrades!
I fully approve of the Politburo report and of the weighty account of the secretary general of our Party. I would like to comment only on one problem, namely, the evaluation of performance. Mention was made of the following issue: In a certain enterprise, the workers produce forgings of reduced weight so that for the identical function they create the same or a

higher utility value; however, on account of the material economy, they then lack the tonnage necessary for meeting the output target and thus are at a disadvantage. The same goes for low-tolerance rolling in the metallurgical industry.

As is well known, the Politburo resolved to introduce--beginning in March--a complex of indexes in the management, planning and accounting of the combines and enterprises and of the national economy as a whole--namely, "industrial commodity output," "net output" and "basic material costs per M 100 of commodity output." According to the report of the Politburo to the 12th Central Committee session, "This will help to implement the principle: What is beneficial for the national economy is bound to be beneficial for the combines and enterprises as well."

Three Indexes--A Single Objective

What does this entail in regard to the aforementioned example of the forge workers? We know that industrial commodity output, the first of the important indexes stipulated in the Politburo resolution, is targeted and calculated on the basis of quality and value. When in the production of forgings the workers save material, they produce in terms of industrial commodity output at least the same value as previously, and the plans are fulfilled accordingly.

Of late, measures passed by the Price Office have come into effect, according to which it will be permissible to raise the prices for thin-walled castings and for low-tolerance rolling in the metallurgical industry; these price hikes will even make it possible not only to fulfill, but overfulfill the commodity output plan.

It has been claimed that on account of the material savings, the quantity fell short 4 percent. If the commodity output is considered separately, this shortcoming persists. For this reason, the Politburo resolved to employ net output as the second important index. Net output represents the value newly created. Thus, in saving material, the forge workers at the same time create a new, higher value. This higher value created by the workers benefits the national economy, the combine and the enterprise; in fact, it also helps the brigade to fulfill and overfulfill its plans.

As for the third index, the basic material costs per M 100 of commodity output decline in this example; for if less steel is used for the same forging, there is a reduction in the costs per M 100 of commodity output. Thus, with reduced material input, commodity output is increased and a greater contribution is made to plan fulfillment. This, too, benefits the national economy and the enterprise.

Benefits for Those Who Economize

The plan fulfillment efforts in the enterprise, in the department, in the brigade and also in the national economy as a whole focus on producing results in regard to the value of commodity output, in regard to net production and in regard to the reduction of basic material costs. This plan fulfillment and overfulfillment underlies the incentives provided for the workers in the enterprise, down to the individual work place. This means that all these measures are beneficial for the worker, for the brigade and for the enterprise or combine and that recognition is effected through incentives. So the worker derives benefit from the identity of his actions with the interests of the national economy, and conversely, the national economy derives benefit from the efforts of the worker.

Comrades, the Politburo specifically pointed out that these performance indexes must be employed as a unit. The Politburo report to the Central Committee states: "Being closely interrelated, the three indexes serve to improve performance." If they are not employed as a unit, but considered separately, we would in the case of the forge workers be confronted with the fact that the tonnage fulfillment falls short 4 percent.

Crucial Problem: Improvement of Material Processing

I have to point out here that the state, the combine, the enterprise--in short, all of us--cannot dispense with the commodity output index. For it is an index that both on the international and the national level is needed by the state, down to the individual enterprise, as an index of quantity and value. And we need exact data as to how many tons of forgings the GDR has produced. For all the considerations of quality, this can only be expressed in terms of tonnage.

Some observers have suggested to calculate a coefficient for the quantity of material saved and to express this coefficient in terms of tons of forgings. This means that we would have to do another conversion involving many difficulties and coefficients. Although it is worth considering, I feel that this approach would divert us from the crucial problem of this and--even more so--the next five-year plan--namely, in accordance with the resolutions of the Central Committee session to improve the material refinement, to create greater value and to turn out more goods, more finished products. Consequently, I feel we should stick to the integral application of these three indexes in the way it has been prescribed.

Modrow on Quality Improvements

East Berlin NEUES DEUTSCHLAND in German 23 May 80 p 3

[Excerpts from discussion speech to 12th SED Plenum by Hans Modrow, member, SED Central Committee and first secretary, Dresden Bezirk Management: "Making the Entire Wealth of Knowledge and Experience Effective"]

[Text] Dear comrades!
With our 12th session, we are entering the phase of extensive preparation of the 10th Party Congress. I can assure the Central Committee that the Dresden bezirk party organization is well prepared and equipped for this new stage of our struggle.

The talks with the comrades have confirmed and strengthened the close ties with the Party, the deep trust of the comrades in our Central Committee and its secretary general, comrade Erich Honecker. They have confirmed the great willingness to make every effort in the struggle for the further implementation of our policy, which is oriented toward the well-being of the working class and of the entire nation.

On the basis of the political fighting positions and thanks to the comrades' example and power of persuasion, thanks to the further strengthening and training of the cadres and the knowledge, skills and commitment of the working people, good results were produced in the first 4 months of this year in regard to the overall consolidation of the GDR, especially in the economic sector.

During this period, the enterprises of the bezirk succeeded in exceeding the industrial commodity output targets by M 106.2 million; to the domestic trade sector alone, they delivered M 36.9 million worth of goods in excess of the plan quotas. During the same period, our construction workers made available to the population 490 new apartments and 119 modernized apartments in excess of the plan targets.

In spite of various difficulties in regard to the feed supply, the cooperative farmers and the other workers of the bezirk's socialist agriculture likewise exceeded all of the plan targets set for livestock breeding.

The past weeks and months provided us with experience and taught us important lessons, especially since we had to work hard for our success. At the beginning of the year, some directors and collectives still raised questions and even made skeptical comments in regard to the requirements of the 1980 plan. In the sharp conflict of opinions, which was triggered by the Party resolutions and which was subsequently enriched by the exchange of experience with the Gera combines, true fighting positions prevailed. Under the slogan of "Plan Guarantee 80," the workers of the bezirk launched a broad movement, in which they identified themselves with the objectives concerning the fulfillment and overfulfillment of the plan.

In this regard, we are also trying to insure plan fulfillment in fields such as the school construction program, in which plan arrears have been tolerated. All our measures aim by 31 May to effect plan fulfillment in these fields.

Progress in Microelectronics

I am in a position to report to the Central Committee that in regard to the implementation of the long-term plans for the development and application of microelectronics in the GDR economy, we have achieved good results. With the establishment of the Dresden Center for Research and Technology/ Microelectronics, large-scale capacities have been created, which under the leadership of the strong party organization are about to produce--in important branches--top-level results meeting the highest international standards. Progress has been made in regard to the improvement of microelectronic circuits. In 1980, all of the targets concerning the development of special technologies in microelectronics have so far been met and exceeded.

We consider all this a good starting position and at the same time we feel it is important to intensify our cooperation with the Erfurt comrades so as to insure that the new Center for Research and Technology/Microelectronics meets all the requirements in regard to work quality and that on this basis we can launch the urgently needed productivity drive for our national economy, which is made possible by microelectronics. Naturally, the ultimate criterion is to what extent we will be able to translate microelectronics into product and production quality and efficiency, to save through the new dimensions working time, labor, energy and material, and with less input to produce more and better consumer goods. This is one of the key tasks of the fighting program of the bezirk Party organization and of the Party organizations of the combines and enterprises.

The bezirk administration is trying to generalize the positive experience of combines such as Robotron and Pentacon and of enterprises such as Radebeul Planeta and Dresden Mikromat and to eliminate the attitude of waiting for ready-made solutions, which is still found in some places.

Likewise, in regard to the development and employment of industrial robots, our bezirk can point to a number of good examples, in particular in the Robotron combine. Through the establishment of shared access, we want to make them more widely available. In this regard, the Dresden Technical University is to serve as a technical center, while Robotron is entrusted with the development and employment of robots in electrical engineering/ electronics, especially in the production of printed circuit boards, and the Fortschritt Combine, with the development of welding robots. Through complex agreements, the Technical University is linked with many partners. Now it is necessary to bring the experience gained in the cooperation with individual combines to bear on a larger framework. After all, what is good for Zeiss Jena, cannot be detrimental to Robotron.

In order to get more out of what we have, it is necessary to intensify in all Party organizations the debate as to how we can effectively convert our great wealth, the knowledge and skills of our scientists, engineers and skilled workers into economic productivity, and in this connection--in view of the impending 10th Party Congress--further to raise the targets of the fighting programs. Even if the pertinent plan targets are met and exceeded, the rate at which most of the enterprises in our bezirk increase the share of new, high-grade products bearing the "Q" quality seal has so far not been sufficient. However, it is only with products embodying scientific and technical advances that it will be possible to curtail and possibly to discontinue the export of material- and working time-intensive products.

Increase Output of "Q" Products

In our bezirk, too, it has been demonstrated that the establishment and consolidation of large-scale industrial combines has considerably improved the conditions necessary for effecting the great and dynamic performance improvement required for our national economy. In honor of the 35th anniversary of the liberation from fascism, the Robotron Combine posted 1 day's output in excess of the plan.

The workers of Dresden Bezirk produce a relatively large share of the GDR's total output of consumer goods. This implies great responsibility for accelerating the rate of production in this sector in accordance with the Central Committee resolutions and, most importantly, for producing more high-grade consumer goods for the population and for exports.

We must systematically improve management work so as to safeguard supplies and we must insure more thorough analyses and enforce quick and responsible response. However, to insure a large output of goods for mass consumption and of high-quality consumer goods is and remains the principal objective. This is the crucial factor in regard to consumer satisfaction, retail trade supplies, and--in large measure--the effectiveness of the performance principle as an important driving force of our development.

In the new phase of our struggle, the Communists and the working people of Dresden Bezirk will do their utmost to continue our proven policy, which is devoted to the well-being of the workers and of the entire nation.

Ziegenhahn: Enterprise Performance Varies

[Excerpts from discussion speech to 12th SED Plenum by Herbert Ziegenhahn, member, SED Central Committee and first secretary, Gera Bezirk Management: "Enterprise Comparisons Reveal Reserves in a New Dimension"]

[Text] Dear comrades!
I fully approve of the directive report of the secretary general of our Party, comrade Erich Honecker, concerning the convocation of the 10th Party Congress and of the Politburo report delivered by Inge Lange.

All Communists and all working people fully approve and energetically support the people-oriented policy of our Party and its ability to wage the struggle for socialism and peace even under aggravated international conditions. As a result of the inspection of party documents and of the personal talks, the Party members' aggressive and disciplined political-ideological work toward implementation of the Party resolutions has been intensified in all Party collectives.

Our bezirk party organization is doing its utmost further to improve the results obtained and--in preparing for the 10th Party Congress--month after month to improve performance. More and more collectives aim through material economy to exceed the plan target by 2 days' output by the anniversary of the establishment of the republic.

However, we do not by any means fail to take into account the still existing, indefensible differences in performance that conceal large reserves to be tapped for the further consolidation of our republic's economic strength. Experience has shown: Wherever the Party organizations head the struggle, wherever they take an unequivocal political position on the tasks at hand and wherever they do their utmost to utilize the qualitative factors, the tasks are accomplished.

The 11th Central Committee session, the speech of comrade Erich Honecker before the first kreis secretaries and the exchange of experience between the Central Committee and the general directors of the combines and the Party organizations of the Central Committee impelled us to help the Party organizations, the economic organs and all collectives more deeply to delve into the economic processes so as to reveal the reserves for performance improvement and to orient the initiatives of the Communists and of all working people toward the crucial chain links of the expansion of economc productivity. This calls for extensive political-ideological work so as to deepen the understanding of complexity of the tasks, to deepen the understanding of the economic-political strategy of the Party and to prepare the Party organizations for the qualitatively new tasks. In this regard, the personal talks were very helpful.

I would like to talk here about certain experience gained in regard to our way of implementing the demands made by comrade Erich Honecker at the 11th plenary session, namely, in preparation for the 10th Party Congress to make the best results of today the social norm for all.

The Combines and Their Net Output

Encouraged by the Gera exchange of experience, we have more intensively concerned ourselves with the question as to what demands are made on the leadership of the Party organizations--from the bezirk down to the Party groups--by the rapid and cogent generalization of the experience of the best workers. Our analysis proceeded as follows: On the basis of the net output produced, what is the contribution of our bezirk, of the kreises,

combines and enterprises to the growth of the national income? What is the rate of production renovation? What is the profitability of our patents and what is the share of top-level achievements in the science and technology plans? What are the orders of magnitude of the reductions in the consumption of basic material per M 100 of commodity output? How can we ensure that labor productivity, net output and the production of goods bearing the "Q" quality seal increase more rapidly than industrial commodity output?

The concrete analyses show the pronounced differences that are rooted in the level of leadership and of the political-ideological work and in the fighting position of the base organizations and of the leaders. Whereas in enterprises such as the Zeiss Combine, the Ceramics Combine and others the share of net output of the total industrial commodity output amounts to over 50 percent and whereas these enterprises aim--through early implementation of material- and time-saving measures based on the science and technology plans--to speed up the revision of the production program in the interest of attaining maximum quality, to make the most efficient use of highly productive installations and significantly to expand their own means of rationalization and thus obtain in 1980 net output growth rates of 10 percent and more, other enterprises such as the Ronneburg Automotive Accessories Plant VEB, one of the bezirk's biggest consumers of basic materials and of rolled steel in particular, or the Bad Blankenburg Antenna Plant show a much lower net output share.

Some comrades claim the conditions they are facing are not as favorable. It goes without saying that one must take into account the differences in regard to starting positions. But on closer examination of this question, it appears--and in this regard the performance evaluation indexes adopted by the Politburo are very helpful--that as a rule the largest reserves for performance improvement are found in those enterprises that do not yet sufficiently utilize the qualitative factors. To change this, it is necessary--on the basis of the experience of the best workers and under the direction of the bezirk and kreis administrations--to exchange experience and compare performance so as to eliminate the marked differences in regard to the level and rate of performance development and to open up reserves on a much larger scale.

Our analysis revealed that the tasks can be accomplished only if they are dealt with as a unit and if they are discussed, defined and confirmed at general meetings. These efforts begin with the establishment of correct standards and of positions characterized by a true Party spirit. Thus it is necessary not only to speed up the development of new products, but also to ensure the lowest possible material input and the highest possible productivity. We must enforce utilization of the qualitative factors--which is the only way to increase the national income and the economic end product. To this end, each kreis administration must thoroughly analyze the performance level of the enterprises in the kreis.

To facilitate the exchange of experience and quickly to disseminate the results, it has proved to be expedient for the kreis administrations to select those base organizations that have the most experience and show the best results in regard to the implementation of the resolutions of the 11th Central Committee session. Study teams and first secretaries of the kreis administrations visit these base organizations, in order to evaluate the positive experience gained in the Party groups, departmental Party organizations and production and research collectives.

The concrete conclusions in regard to utilization of the experience of the best workers, including the new performance targets, are discussed and confirmed by the base organizations and the study team of the kreis administration. It is imperative that the kreis administration adopt an unequivocal position on the objectives to be pursued by the given Party organization and enterprise collective. Thus, through the kreis administration's systematic leadership, the achievements of the best workers are cogently generalized in the base organizations with due regard for the given concrete conditions, while in the enterprises there are elaborated the measures concerning the great performance improvement at the important next stage. On this basis, the base organizations and the kreis and bezirk administrations are presently developing their measures, contribution and program regarding the preparations for the 10th Party Congress.

Long-Term Decisions

It is apparent everywhere: Today any exchange of experience necessitates in all Party organizations an uncompromising struggle for the accomplishment of the tasks established; it also calls for the ability self-critically to evaluate one's own work and to measure it against the standards set by the best workers. Thus it is necessary not only to recognize the results produced by the best workers, but also unconditionally to adopt them as standards of one's own performance. To this end, it is necessary to work out the changes required and to make long-term management decisions.

After the bezirk administration session and upon evaluation of the results of the 12th Central Committee session, the innovators and efficiency experts will at the 6th bezirk conference in June discuss and confirm the qualitatively new targets on the basis of the program of the bezirk Party organization and of the expanding mass initiative. Thus, under the leadership of the Party, the best representatives of the ruling class determine the pace of our further successful development.

ECONOMIST ANALYZES POSITIVE, NEGATIVE EFFECTS OF REGULATORS, THEIR INTERPRETATION

Budapest VALOSAG in Hungarian No 8, 1980 pp 38-46

[Article by Laszlo Bogar, economist and group leader of the Executive Committee of the Borsod Megye Council: "Interest Relationships, Secondary Economy, Corruption: An Attempt to Discover the 'Hidden' Dimensions in Historical Processes"]

[Text] One might say that in the course of recent years the expressions figuring in the title have become fashionable concepts. More and more scientific works deal with uncovering them but interest in them is increasing even at the level of everyday awareness. All this is not at all by chance. These concepts and the linkage systems which bind them together are important links in the self-awareness of our society. Today, when the need for change and the necessity of renewal permeate our economic and social relationships, it is most important that we form a precise and detailed picture of ourselves for the strategy of change can come into being only with a fundamental discovery of the reality of the present.

With my following thoughts I would like to prove that a basic analysis of the concepts in the title and a historical study of the interdependencies between them is an important condition for becoming oriented in our present social relationships. I think that in many areas the social sciences have failed to give a satisfactory answer so I would like to speak about the reason for these deficiencies and about the possibilities for a solution.

The fact that the picture which our society has formed of itself is somewhat deficient is well illustrated, I feel, by the fact that in the course of past years the effectiveness of our very important decisions passed at the highest levels has broken on the resistance of reality.

The question arises, why have those difficulties facing our national economy and in a broader sense Hungarian society as a whole concentrated together just now?

In the first place there certainly are world economic factors involved. But we would be off the track if we thought that the source of our troubles was the economic crisis of the capitalist world. According to this logic we would have to make the world economy "responsible" for our accelerated economic growth at the end of the 1960's because it was the western boom which, in part, made possible our noteworthy development.

In the second place we must admit that the Hungarian economy was not capable, either at the end of the 1960's or today, of flexible accomodation or quick reaction and did not produce at a level which would have made it capable of at least maintaining the world market positions attained. If we broaden the historical horizon we can say also that according to some calculations the terms of trade of the Hungarian economy have deteriorated by about 70 percent as compared to 1913--thus, the period preceding World War I. In general this means that today the world market values each unit of Hungarian work lower by 70 percent than it did 65-70 years ago. Discounting brief periods of stagnation, this means that the world market positions of our economy have constantly deteriorated and the deficits it suffers have gradually increased. So the real problem is not that all sorts of changes--sometimes very swift ones--take place in the world economy but rather that in the most varied periods of its development the Hungarian economy has found it difficult to give a constructive response to the challenge.

The lack of flexibility of the Hungarian economy is not at all a unique phenomenon among the socialist countries of central and eastern Europe. This complex of phenomena has very deep roots--going back over several decades--so it is natural that I cannot undertake a detailed analysis in the framework of this brief study. But the prospects for the development of CEMA integration depend to a large extent on whether we are capable of jointly and separately discovering the historical roots of the economic policies followed in past decades so that our strategy should overcome the limitations deriving therefrom.

In general it is characteristic of these countries that after the vexed and tension-filled social processes following World War II the progressive historical forces--with essentially bloodless actions--took power in 1947-1948. But seizing the positions necessary for the exercise of political power put the guidance of society before a necessary dilemma.

This historical question mark was not something new. The large scale debates of the 1920's in the Soviet Union sought answers to the same questions. And although the outlines of the answer seemed to be developing the ramming through of central measures--not independent of international developments--put an end to the debate.

What sort of dilemma are we talking about? To understand this we must review one of the basic equations of the classics of Marxism--one which explains the dynamics of the development of societies. According to this equation the unbroken development of the productive forces of society from time to time necessarily clashes with those social relationships the

relative stability of which is an indispensable condition for the existence of certain social-economic formations. To the extent that the existing relationships slow down the development of the productive forces to an intolerable degree the frameworks of the relationships will be broken down via the infinite dimensional transmission system of social-economic interdependencies, building new fields of movement on the ruins. This classical example of the application of the method of dialectical materialism is very well known and a vulgar adaptation of it is familiar even to high-school students. But in the course of its frequent repetition it was almost completely forgotten that the dialectic is valid in general for the analysis of processes and does not go in one way only. In the given case, for example, it also "goes backwards." Thus, if we hypothesize that we want to "operate" the given productive forces in many times more developed and qualitatively different production-social relationships then according to the laws of dialectics the productive forces will bring down to their level those relationships which are really more developed in regard to their theoretical essence. Let me note that we should treat the expression "want to operate" with suspicion because objectively the productive forces determine that zone of relationships in which they can develop or even function and if we arbitrarily designate the boundary values of the zones on the basis of a subjective wish we can regard the difficulties of this undertaking as assured over the longer range. This is true also because the relationships are always relationships among the objectively existing elements or sides of the productive forces and thus are the relationships of the given productive forces.

At the end of the 1940's the victorious political forces necessarily faced the apparently unsolvable dilemma when they wanted to institute developed socialist production-social relationships, in accordance with the political structure which had developed, in countries with backward and undeveloped productive forces. But there were only a few months--as compared to the time taken by the Soviet debates--to develop the action alternatives deriving from this and the debates did not take place on the surface but rather in the deeper and more hidden spheres of the developing social systems. Naturally, in the given historical situation--with the spread of dogmatism--there was very little likelihood of another alternative but still we must state that after the general progressive victory--and in the course of a swift polarization process--power went with surprising suddenness into the hands of forces which conceived the theory and practice of the guidance of society in a voluntarist manner. It is a historical paradox that the existence of the Soviet Union created the political-military conditions for the creation and development of the people's democracies while the power of its example at that time almost immediately determined the paths of this development. Thus, without debates and the social experiments deriving therefrom, the execution of the people's democratic program could be carried out only with the aid of voluntaristic guidance systems which even in their view touched the border of irrationality.

I might note that the leaders of society at that time actually recognized the tension built into the balance condition of society but--as a result of the logic of the situation--there could not be a suitable solution.

They imagined that the militant revolutionary elan and self-awareness of the masses could be the ideological "footstool" on which the undeveloped productive forces could "stand" to "bring themselves up" to the developed production relationships. We can "thank" this theory for the Stakhanovite movement, and for the superficial methods, filled with unjustified optimism, of the early labor competition and other movements.

This voluntaristic model, which virtually stood reality on its head, produced distortions in both material processes and social awareness the harmful effects of which can still be felt today.

In my opinion a common cause for these effects can be found in an important motif of the incorrect answer given to the already mentioned historical dilemma. We might call this motif--with a somewhat forced expression--the "oversocialization" of productive forces. (The expression might be challenged--primarily liguistically--but the concept designated by it can hardly be challenged.) We should add that naturally there is no scientific economics method with the aid of which one could precisely determine what degree of socially organized operation suits the given developmental level of the productive forces. But the experienced facts give us sufficient reason to hypothesize that the period between 1948 and 1953 did some violence to reality and created a level of socially organized movement of the given productive forces--which were very undeveloped--which can be regarded as a distortion of socialist economic development as a whole.

It has been proven innumerable times in the course of history that when reality is "attacked" it will defend itself and the "immune reactions" have accompanied our entire economic development since. Considering, however, that there still has not been a more profound analysis of the real circumstances surrounding and the roots of the development of the voluntarist economic policy our knowledge of these latent consequences is still dim and uncertain. But we have experienced their negative effects intensively in recent years. It is not at all by chance that research on the group of phenomena summed up under the name of the secondary economy has accelerated recently. In essence the secondary economy is a collective concept for the non-socialized forms of activity and as such it can be closely related to the above mentioned "immune reactions."

In the period between 1948 and 1953--as I have mentioned already--the socialization of production reached too high a level which could be maintained only by the force of a voluntaristic economic policy. And this only apparently. Because while it is true that in those times--and certainly since--the non-socialized forms of activity were to be condemned from the ideological viewpoint, were politically suspect, and thus their open practice seemed risky in general, the "only" thing that resulted from this was that "being outside socially organized distribution," as one of the basic criteria of the secondary economy, gradually became incorporated in the organizations of the socialist sector. Naturally this process could take place only in a very hidden form, at the price of innumerable deformations, which produced consequences hardly recognized thus far in the entire system of the socialized sector. From the economic viewpoint the effect of economic

policy was to force the non-socialized sector into too small a sphere of movement. To use a physical simile, the pressure increases in a compressed space--the result of which in the case of our theme is a double transformation. On the one hand the movement of the economic "molecules" accelerated extraordinarily in the non-socilized sector which existed legally but which justly felt its legality to be uncertain. What will be characteristic is a mentality which encourages living for the moment, get rich quick, looting and a wasteful life. On the other hand the great pressure virtually "forced" elements and characteristic movement forms of this sector into the socialized sector. It appears from all this that for a long time politics can ignore economic laws and hinder their realization, but there are consequences of this. And yet--as we have seen--these laws--which naturally cannot be abolished--have a diverting effect beneath the surface.

These effects produced not insignificant changes in the socialist sector and the real internal interdependencies of it--we are really feeling this only in recent years--are not at all as they are described by our political economy textbooks. Unfortunately we know very little about what they are really like. The excessive socialization of the productive forces, which naturally was accompanied by excessive centralization, was actually based on an unshakeable faith in the omnipotence of the center. If--the unspoken explanation went--social property is absolute and if it will take the form of fewer and fewer giant enterprises then the center, without any great difficulty, will be able to realize the social interest represented by it in the course of running the economy. And if we are talking about interests we must stress that the Marxist social sciences have not provided a many-sided analysis of real interest relationships in a socialist society--perhaps because of the increased political sensitivity.

The voluntaristic policy of the 1950's made prevalent the idea that there was no place in the system of socialism for differences of interests--not even to speak of interest conflicts. This illusion which forced interests into a false unity was based on two dogmas.

The one hypothesized that every particular interest in a socialist society was a harmful, individualistic remanant which stood in opposition to society and as such was to be eliminated by persuasion, education or the tools of force. The other dogma was the hypothesis that under all circumstances the central will would perfectly express the social interest and was the only possible form of its manifestation.

The common--anti-Marxist--basis of these two principles was a denial of the objective existence of differing interests which was expressed by forcing onto practice the illusion of a socialism free of separate interests.

It is thus understandable that the policy of the 1950's, which tried to present the interdependence of interest relationships as a harmonic unity and presented as realized something the conditions for the realization of which were not given, held back the development of the self-awareness of society as truly reflected by interest relationships.

The political atmosphere of the past two decades has made it possible for us to come to the recognition that the interest relationships of the socialist society are structured and derive from the structure of this society itself. But this recognition has not yet at all pervaded the view governing the guidance of society and the economy. This is why--as Lajos Hethy writes in one of his articles--it is recognized and emphasized in words at most levels of guidance that "lower order" group and individual interests going beyond the all-social interest do exist in our society but people still frequently act as if the basis for their activity were exclusively the "higher order" social interest, as if the existence of other interests were some sort of undesireable state of affairs which must be overcome. Declarations concerning the structure of interests and the recognition of the existence of interest differences and even interest clashes does not at all mean in itself that thinking in terms of interests and interest relationships has become an organic part of the social conception of guidance. What is absolutely necessary for this is thinking in terms of changing interests, in terms of their movement mechanism, without which references to interests are merely a basis for allusion, an ideological disguise, which tries to put a modern mask on an obsolete view of administration and guidance. The picture formed about the role played by interest relationships in human action and the traditional guidance and administrative ideas formed about the functioning of organizations co-exist in the "thinking" of guidance. And since the latter have much deeper roots in our views, in our political and social practice and in our historical traditions than does the conception of the structured nature of interests progress runs into difficulties.

But if we accept the formulation of Engels according to which "... the economic relationships of a given society appear before all else in the picture of interests," then our conclusion can only be that the lack of thinking in terms of interest relationships is equivalent to weak "vision relationships" and faulty "road signs" in the major relation systems of society and thus equivalent to deteriorating chances for the solution of the problems.

To sum up what has been said thus far, the dogmatic political leadership of the 1950's turned our social-economic processes, in part, into a mistaken bed, into a bed alien to these processes. This created severe distortions in the entire system of social-economic relationships, the symptoms of which can still be felt even today. The substantive transformation of the economic mechanism in the course of the past 10-15 years and the processes set in motion by this have indisputably created a favorable atmosphere for the elimination of these mistaken relationships. But the compromises of the reform measures made possible the survival of a few such remnants. The first motif in uncovering these remnants may be an acceleration of research dealing with the structure of interests and their link to the decision mechanism and the organization of guidance. I would like to prove with the following train of thought that the creation of pure "vision relationships" for society is not merely an end in itself, not some sort of humane gift or some new showy act in the spreading of democratism. This train of thought is also an experiment in the apprehension of the mechanisms of corruption.

The social-economic reality--as we have seen--responds with a unique "immune reaction" to the effect of the voluntarist policy. In our case this defensive mechanism is a process in the course of which there appears in the organizations of the socialized sector--first in some layers of the activity taking place here but then permeating the entire organization--a "being outside of socially organized distribution" as one of the basic criteria of the secondary economy. This process even appears in the organizations of the "most socialized" sector, in the organization of state administration and state power.

Considering that according to the most general formulation we are accustomed to refer to the "distortions" of the social distribution of goods under the comprehensive term "corruption" we can view the distribution distortions appearing in the organizations of the socialized sector--which come about as a result of the above mentioned processes--as increasing the chances for a corruption of the system. To make the definition somewhat more precise we might say that we can regard as corruption any act in the course of which the person responsible violates the distribution system based on social consensus for the benefit of others and in the expectation of some recompense therefor.

In what follows I will try to examine who becomes a participant in corruption and under what conditions, thus becoming a factor in the secondary or even "third" economy.

If we examine more closely what we have just said about the nature of corruption it is impossible not to notice that we are faced with a unique conflict of interests. In the final analysis, if the distribution system based on social consensus is violated anywhere this means that someone is violating the just interests of a higher order interest sphere, encroaching on its goals, for the benefit of his own interest community or directly for the benefit of himself. It seems logical, therefore, that the possibility of corruption is greatest for those who have the ability to realize greater, broader interests. With a certain constraint the professional sociological literature equates the possibility of realizing interests with the concept of power, so with some simplification we can say that the number one condition for corruption is to have power. (However trivial this statement may appear!) In the social system of the division of labor those have power who dispose of and exercise control over the distribution of certain material and moral goods, who stand at the "sluice gates" of the distribution channels. The higher the position occupied in this system of the division of labor the more important, qualitatively and quantitatively, the goods over which one has control and thus the ability one has to realize interests is substantially greater.

Let us note here that generally recognized interdependency, which is formulated in the works of the authors Hethy and Mako, which shows that the contemporary view of guidance in judging the ability to realize interests is characterized by a unique mixture of naivite and voluntarist determination. What we mean is that, whether it is said or not, there is

an idea according to which the abilities to realize interests are nicely stacked up in a great central warehouse and everyone receives as many of these abilities--in accordance with the strictly controlled directives of the center--as are absolutely necessary for the successful filling of the position occupied by him in the social system of the division of labor. This conception--unfortunately rather general--completely ignores the interdependency according to which guidance does not set the processes of reality; on the contrary, reality determines the possibilities of guidance. But we do have some initial experiences concerning the complex social system for the development and functioning of the real abilities to realize interests.

The very dim and imprecise picture of the realization of interests is an important constituent in the response to our basic problem because it increases the uncertainty in research on the sources of corruption. It is natural that the greater the difference between the real ability to realize interests and the ability hypothesized by central guidance in the case of a given group or individual (let us hypothesize to the benefit of the former) the greater the possibility that the individuals or groups involved will have uncontrollable freedom of movement and action in the hidden dimensions not presumed to exist officially. This uncontrollability potentially increases the possibilities of corruption.

Another important motif of the interdependency is that not only will the chances of realizing interests increase for those occupying a high place in the social system of the division of labor but there will also be an increase in their possibility of presenting their real individual or group interests as the interests of a much broader community (the megye, the national economy, etc.). This very general phenomenon is linked to that very tenaciously surviving dogma according to which the higher hierarchic level represents higher order interests under all circumstances, indeed that general interests can be formulated only at a higher level. And, of course, here one finds the other side of the interdependency, already mentioned, from which it logically follows that every openly particular interest is harmful, an individualistic remnant, which is opposed to the interests of the higher order communities and as such is to be abolished by persuasion and education or with the tools of force. The contemporary conception seems to have distanced itself substantially from this view because we have come to the recognition that the interest relationships of our socialist society are structured and that this derives from the structure of society itself. But the conceptions followed in the aministration and guidance of society and of organizations therein have not yet been brought into suitable harmony with this recognition.

Thus, to sum up, we can state that the information we have available concerning the real mechanisms of interest relationships and the chances for realizing interests is very limited but in a unique way, in the case of our theme, this statement seems essential because it is precisely this uncertainty, the unknown elements, the lurking suspicions, the formalized surface which only hides the already mentioned hidden dimensions and arouses

distrust which are all of them important conditions for the development of corruption.

Naturally, the picture would be somewhat one-sided if we approached the question only via interest relationships. It is well known that in the final analysis human motivations are determined by a very complex and difficult to discover mutual effect of interests, values and feelings. We have just seen that the system of distribution based on social consensus can be distorted by the fact that under present conditions as one rises in the hierarchy there is a swift increase in the chance to realize individual interests which damage the common interests, to present this act as activity serving high level interests and, in a paradoxical manner, to win material and moral recognition for this. On the level of motives this is only the possibility for corruption; whether a given individual actually becomes corrupt depends on the extent to which his value system and his associated feelings determine his behavior. Naturally one could write an independent social psychology study about these questions so I would risk only a few observations here. As in every definitely transitional society in the process of formation so in our system also very heterogeneous value systems develop; feudal, quite atavistic, bourgeois and socialist value systems, this last still existing in part only hypothetically and burdened with the dogmatic inheritance, exist side by side in a system of open or hidden conflicts. The virtually complete lack of historical roots for human communities with self-regulating, democratic traditions also deforms our human value systems. The problem is increased by the fact that instead of discovering the real interdependencies of the political practice of the initial period of the building of socialism they were often covered over by a popularization of an artificial surface. As a result of this, among other things, there developed a type of man and an idea of man which were rather disillusioned and cynical--thus "not paying attention" or apolitical but still maneuvering among the everyday ceremonies of the dogmas--in the final analysis antisocial and incapable of cooperative strategies.

I believe that it is not necessary to offer any special proof that this unique situation unambiguously favors the existence of corruption because on the one hand the natural control of people is dissolved or does not come into being and, what is more important, there is no incentive which would favor non-corrupt behavior.

As a result of very complex processes which cannot be analyzed in detail here there may develop a public sentiment which condemns manifestations of corruption formally only because it has been left out of it. There comes into being a sort of schizophrenia which makes it possible for a single individual to peacefully accomodate what is routinely corrupt while officially and with conviction condemning and persecuting other manifestations of corruption. So it would be an illusion and self-deception to believe that the decisive majority of our society rejects corruption as a phenomenon alien to socialism. This cannot be because, in the first place, this phenomenon is not at all alien to the present, actually existing

socialism--at most it may be to an idealized abstraction of it--and in the second place under present circumstances the frequent acceptance and everyday use of some form of corruption is a social necessity which cannot be stopped, the chain reaction of which cannot be reversed, by the insight, good intentions or cooperativeness of individual people. He who takes himself out of this chain will lose--whether he like it or not. So there can be no doubt that for some time to come the social trap of corruption will be a basic problem of many societies, including our own.

Thus far we have concentrated on the subjective side of corruption and on the immediate causes and possibilities determining it. Let us now examine what additional causes contribute to the development of this phenomenon. It is very frequently said in connection with corruption that the shortage of some commodities is an important external condition for its existence. One can easily see that there is a much greater "temptation" to "correct" distribution in one's own interest in the distribution of goods available in limited quantities than there is in other cases. It is also rather well known that it is customary to call the economic system of socialism a shortage economy. The incentive for corruption from this side is most unambiguous. But in the interest of finding a way out it would be better to think through this interdependency--the extent to which the shortages appearing in socialism can be regarded as natural, organic shortages and the extent to which they can be regarded as the consequences of demand, frequently an over-demand, which is sometimes anarchic despite the apparent complete control, actually over-regulation which has lost control.

Once again it would not be unprofitable to examine the historical roots, because the key to the over-demand hides in the basic characteristics of socialism. It may exist in that still unsolved dilemma which involves how to base a strategy of dynamic economic growth on two rather contradictory axioms, namely that we would like to preserve the "ideological purity" of the silk purse character of the phenomenon but would like to make all this out of a sow's ear. How this will succeed and when is a historical question mark but one thing seems certain, that in this way progress will be increasingly protracted. Our economic policy paralyzes the crucial functions of the law of value--without the realization of which there is no commodity producing society--with sometimes unlogical inconsistencies which make it impossible, for example, to stop the spinning of the above mentioned abnormally overheated demand. It could be stopped only by giving up another political axiom, the principle of swift growth. Without pursuing this any further let me note one interdependency, namely that in the economic system of socialism thus far there has not been any real economic limitation to the unrestrained over-demand for the factors of production. This necessarily led to a shortage economy and the economy of shortages necessarily encouraged the tendencies of corruption.

Among the external causes of and conditions for the existence of corruption we should deal in some detail with another important factor which is tied in in several ways. It is a phenomenon which can be observed around the world that corruption flourishes primarily where the principles for the

distribution of goods are not sufficiently clarified and where there are those who have made people believe that this or that decision depends on their judgment, inclination or pleasure. And since their real ability to realize interests is much more extensive than the social control hypothesizes this is often true.

I note in passing that despite all appearances it does not seem excessive to state that we have a rather superficial knowledge of many important relation systems of the social and economic system of socialism. There is a quite obvious explanation for this lack of knowledge--there is simply little historical perspective and relevant experience. But there is another reason too which is a substantive problem because the fact is that a sort of bureaucratic rigidity is characteristic of the entire system of socialism--as it has been of every society thus far. There are very many people whose interests and feelings tie them to certain interdependencies which may have been important achievements in their time but the present role of which is strongly retrograde. All of this holds back a discovery of the real relationships and the defective nature of self-awareness can be attributed either to society itself or to those institutions and relation systems of it which have outlived their time. And no organization can regulate itself with sufficient efficiency with a self-awareness which is defective and greatly impeded in its development.

Because--to return to the original question--it is in vain for the rules coordinating the distribution processes to be unambiguous if their execution is uncertain and arbitrary. In this case the result--or lack of result--will be the same. Any type of regulation can fulfill its function only if it first knows with merciless sincerety the slice of reality to be regulated.

If it neglects to do this--or if it does it only superficially--then the regulator system may be apparently perfect and consistent but its effect will break on the resistance of interdependencies contrary to its hypotheses. Regulation does not move the social processes; these processes will realize themselves following their own objectively existing internal laws. Thus, guidance and regulation are capable of influencing the objective course of affairs--for example, the development of interests and of possibilities for realizing interests--only to the extent that their nature permits; in other words, the existing reality can be regulated only to the degree and in the way made possible by the internal laws of its autonomous movement.

One should neither over-estimate or under-estimate the possibilities of social regulation in this. There can be no doubt that regulation cannot substantially change the abilities to realize interests--without the risk of harmful consequences. But it is capable of and it must be suitable for building up and constantly maintaining those zones in which the most varied interests can confront one another as the result of the clash of which there can develop interest compromises and consensus which have a progressive direction for society.

Constant maintenance is very essential so that regulation can flexibly follow the development of economic and social relationships by modifying the rules. Because if it becomes rigid it will become a brake system in a short time and the dynamic aspirations for development must seek possibilities for progress on byways, possibly on roads which have been distorted into corruption. The chief problem here is not that some sort of corrupt practice develops--which may be useful for a time--but rather that over the long range corruption will undermine and parlyze these aspirations and slow down and hinder development as a whole.

There are signs of "rule inflation" these days in that the presently existing system of economic-social regulation can satisfy these requirements only to a limited degree and thus despite our over-regulation we frequently become unregulated and thus our decisions will be, in part, unrealistic.

It is natural that in the atmosphere thus developing moral inhibitions are weakening because of the psychosis of uncertainty and arbitrariness. And although we have already mentioned the interdependency of social awareness, value system and corruption it would not hurt to note again from this side that it is a difficult task in our society to form and constantly renew those norms, that totality of action rules, which make possible in every area of life the passage of unambiguous decisions. Many contradictory or at least incompatible principles and facts cross one another, extinguish each other's effectiveness, and as a result it is impossible to control human behavior. No one of them has sufficient content or force, not one of them is strong enough to bring into some kind of order or socially harmonize the multiplicity of constantly proliferating momentary interests. Corruption easily flourishes on the soil of this weakness of the value system.

Returning to the theme of regulation, the social system of regulation must better stimulate the creation of economic, social and political structures and institutions which can mediate among the various strata and groups of society, which are capable of effectively concentrating the information needed for successful decisions, which can create and systematically maintain the clash and play of the aspirations of the most varied interest groups. In part institutions capable of this never existed in our society; in part they have weakened as a result of the swift development.

There can be no doubt that today we have gone--at least in words--far beyond self-satisfaction; but social practice still often suggests this. The disadvantageous development of external and internal economic conditions, however, does not make it possible to maintain this practice any longer. The real springs of social processes must be made clearly visible to everyone; only in this way can everyone find his own place, the possibilities for putting in motion his human energies. In the future we will have ever greater need for the concentration of energies, for the free development of the abilities hiding in people.

BANK OFFICIAL DESCRIBES REQUIREMENTS FOR EXPORT DEVELOPMENT LOANS

Budapest NEPSZABADSAG in Hungarian 10 Aug 80 p 3

[Article by Istvan Dancs, business director, Hungarian National Bank: "Export Development Loans"]

[Text] The presidential board of the Hungarian National Bank discussed recently the experiences in the use of the credit line known as the 45-billion program, and concluded that this has been the most successful credit operation in the last 12 years. This huge sum aids primarily the implementation of investments in export development. Its use is thus a great contribution to the improvement of our foreign trade balance. And since only modern, constantly high-quality and profitable goods may appear--and be competitive--on the world market, these investments also promote a faster turnover of products and increase the organization and profitability of production. It is characteristic of this form of credit that its conditions were not determined individually for each branch, but were presented to all enterprises and cooperatives as a unified norm. This means that competition for credit also increased; the bank's strict requirements can be met only by those firms which are in good or excellent condition.

Fifty-one Billion Instead of Forty-five Billion

In spite of stiff credit requirements, enterprise and cooperative investments were lively in the first 3 years of the present plan period. The majority of the applicants thought that they could finally implement their old pet development projects through our program (for the stiff requirements were accompanied by certain benefits). Although the bank tried to give, through strict selection, preference to proposals that were most profitable for the national economy, our money allocated for this purpose was gone by 1978. Then the government, seeing that this form of credit was successful, allowed us to extend the credit margin by 8 to 10 billion forints until the end of the plan period.

By the middle of this year, more than 1,700 investments had been started --mostly in export development and, to a lesser degree, in import

reduction--with a credit of 51 billion forints and the enterprises' own resources, totaling 90 billion forints. By the end of 1979, 37 billion of that has been finished. The food industry and agriculture used most of the credit; the cooperatives filed mostly joint applications. In the industrial area, the machine and chemical industries took the largest share: the investments there were very concentrated, 40 percent of them being made up by 10 large-scale investments. The significance of the program is indicated by the fact that these investments resulted in exports amounting to $870 million, which is 13 percent higher than planned. Foreign exchange revenues are also a good illustration, i.e., when we deduct from the value of production the value of the imports necessary for production; this is 15 percent higher than the enterprises had hoped for. All of this means that the investments' time of return from the net foreign exchange revenues is, on the average, within 3 years. In short, one-third of these investments has already been paid back in full.

It must be added to all of this that, although these developments can no doubt be considered better than usual, the quality level of their implementation is not even: 25-30 percent of them had problems in cost estimation and market evaluation. Investments involving large constructions are especially affected by the weaknesses of the domestic investment market. It says much in itself that the spirit of enterprise suddenly increased in 1976. This was not always beneficial to the requirement of thorough preparation: it resulted in a danger of frittering the assets away, in extra costs, and in a slow-down of implementation, especially at larger constructions. The development of insecticides and pesticides at the Kobanya Medicine Factory involves significant extra expenses and thus it will cost 60 percent more. The development of the poultry processing plants of Kikunhalas, Debrecen and Zagyvarekas and the Nitro-Chemical Industrial Plants became more expensive for similar reasons.

But the passing of time not only increases the expenses, it also endangers the developmental goal. In a few cases the investors made an incorrect market evaluation, that is, they were not careful enough in selecting the imported technology. There are now six investment projects underway which make protein imports unnecessary. These will require new technology, for the existing technology does not work well. The Finnish press bought for the ERDERT's Vasarosnameny fibre-board plant broke down during the initial testing.

The Goals Are Being Achieved

The constant capitalist depression also plays a role in the problems of the market. This is why there was tension in the case of the MOM, the Csepel Vehicle and Bicycle Factory, the Jaszbereny Refrigerator Factory and the Orion plant. The lessons are manifold. What is most apparent is that the business deals are too one-sided, there are too few export

proposals connected with stable cooperation in trade and production, and thus the domestic enterprises are at the mercy of their partners. I think it is a mistake that, although the regulation makes it possible, the interests of the producer and the foreign trade enterprise are still seldom identical, and that the entire burden of the risks are mostly carried by the producing enterprise. The associations that are being created presently may indicate a step forward in this area.

The credit program has achieved a market-oriented development, which was its main objective. In addition to exceeding the export targets, we were also able from the middle of the plan period to appear on the market with really new products, such as, among other things, the secondary metallurgical products made with a technology that is efficient in the use of material and energy, e.g., thin pipes or highly efficient chemical materials, herbicides and pesticides, and certain important chemical intermediaries. These are, however, only the first swallows. Unfortunately, however, there are still enterprises which still use today's technology to manufacture yesterday's products: they connect the "what" with the "how"--not the other way around. A steady improvement of our terms of foreign trade cannot be expected with this kind of export. For this reason, we will give more support in the future to the manufacture of new and viable products which are the results of more mental efforts.

Because of the stricter regulations, the profits of certain enterprises are lower than planned. This tension is highest in the machine industry. Also instrumental in this is the fact that while the government adjusts the prices to the changes in the world market--that is, it conducts a sensible anti-inflationary policy--the majority of the enterprises still do not know how to deal with this effort, they still do not feel the possibilities of exchange economy. It is a fact, of course, that this would require not only an increase in exports, but also better labor management, a decrease in production costs, and conserving of energy, material and manpower. It also must be noted here that, especially in the processing industry, the expected export profitability of an investment can hardly be estimated and cannot be separated from the enterprise's entire activity. Even the credit-lending bank is put off in these cases. The real guarantee for the obligations and output is the enterprise's entire previous activity. All of this is a warning for us that we must evaluate every new developmental goal in connection with the enterprise's entire activity.

Unfortunately, few small and mid-sized enterprises and cooperatives are taking part in the program, although we agreed with the National Federation of Artisan Cooperatives 2 years ago that we would help flexible and rapid undertakings in many ways, if only to eliminate the problems of the supplier industry. The slow pace of moving forward is explained by the fact that some of the smaller enterprises did not submit any proposals for evaluation and others are deterred by the requisites or do not think they will get the credit even when their proposal is good and

economical; they do not know that the bank does not always insist on the specified degree of self-contribution. These developments are also hindered by the fact that the enterprises which export finished products do not, with a few exceptions, pay back a specified percentage of their extra profits to their cooperating and outside associates. We would encourage this kind of joint effort; several enterprises may submit joint credit applications in the future.

I think the weakest area of the development program is the administration of import-substitution investments. We also gave credit for this kind of investment, although not too often. The revenues from these, for the time being, lag somewhat behind the expectations. But in general, we ourselves rather supported the development of exports, although the area of economical import substitutions also has many hidden resources. It will suffice to refer only to our investment possibilities in sensible energy rationalization, which substitute for expensive imports of hydrocarbons. True, our enterprises did not make any exact estimates either, as to what parts and part units they could manufacture at home. However, the only worthwhile import substitutions are those which are as valuable as the imported competitor, and it does not hurt either if they not only improve domestic supply, but also make a certain amount of exporting possible. This is why the bank will also encourage the enterprises in the future to take such credits if the economy of the import substitution is proven or easily measurable.

New Proposals

The export development program as a whole did fulfill the hopes for it and thus it will be worth maintaining this credit structure in the future without any significant change. According to the plans, the export development credit, with a slow-down of the pace of investments, would be 60 to 65 billion forints, which is about half of the expected total credit limit in 1981-1985. In my judgment, we can continue to contribute to the improvement of our country's international balance of payments only if we do not ease the strict credit requirements, but are more flexible with regard to the conditions and consider the financial situation of the enterprises and the wider possibilities of management. The program's success also urges us to use the experiences gained in export development investments in other areas of credit lending as well.

Finally, let me mention that we have not used up the 1980 credit limit entirely, because the enterprises are waiting. This is partly understandable since they are just getting familiar with the effects of the new regulations and the new price system, and they do not yet see the possibilities of the next plan period in their entirety. The trouble is that credit is not even being sought by enterprises which would be competitive in the long run because of efficient production. But we would like to avoid the credit slump resulting from the change to another plan period. It is not campaigns that are needed to hold onto

and extend our existing market positions. What is needed is systematic work in market and technical investment development.

Our primary expectation regarding this year's new price and regulatory system is that it will improve our clearsightedness in evaluating the enterprises. We will now be better able to select from the submitted development proposals the economical ones which deserve a bank credit and even a state subsidy. In order to keep the spirit of enterprise alive, we must coordinate the possibilities of our credit and subsidy systems and our methods.

REGULATORS COMPLICATE INTERESTS OF GRAIN GROWERS

Budapest FIGYELO in Hungarian No 33, 1980 p 11

[Article by Gyorgy Koranyi: "The Changing Interests of the Grain Industry"]

[Text] In order for the Grain Trust to obtain as much in the development fund from profit as it did last year, it will need a profit of 373 million forints, that is, a 43 percent bigger profit than last year. But the area of expenses does not provide as much room for formation of profit as before. The regulators introduced on 1 January changed the economic interests of the grain industry in many areas. For example, in 1979, 18 percent of the average tax on profits could be retained to form the development fund, which represented 6.8 percent of the profits. But this possibility was eliminated in 1980.

The obligation to pay progressive taxes has also changed. Formerly, formation of a dividend fund of up to 2 percent of total wages was still tax free. Since 1 January, however, a 200 percent progressive tax must be paid even after formation of the dividend fund of between 0 and 2 percent. (Profit appears in the denominator of the profitability index, and the numerator is the product of the net value of the equipment inventory and the chronological average of the total inventory plus the annual total wages.)

If, on the other hand, the profitability index reaches 2 percent, but not more than 4 percent, then 0.5 percent of the dividend fund formed is tax free; in the case of profitability between 4 and 6 percent, 1 percent is exempt from the progressive tax. For every additional 2 percent increase in the index, another 0.5 percent of the dividend fund is exempt from the progressive tax.

The average profitability index of enterprises in the grain industry this year is expected to be between 4 and 6 percent. Therefore, approximately 1 percent of the dividend fund will be exempt from the progressive tax.

A further significant change is that only 60 percent of the yearly allowance for depreciation or amortization goes into the development fund, instead of 100 percent. Through the centralization of 40 percent of the amortization, the possibility of formation of development funds at the trust level has been reduced by some 190 to 195 million forints.

Wage regulation has also changed significantly. In enterprises working under the system of regulation that ties total wages to enterprise output, the average wage (wage level) can increase tax free by 3 percent more than the wage increases possible on the basis of the output index. For example, if in a particular enterprise the value added rises by 15 percent compared to the basis, then total wages can rise by 4.5 percent, and the wage level by 7.5 percent, free from the wage-increase tax.

By the terms of the regulations of 1979, taxes must be paid in every case in which wages rise by more than 6 percent. Under the new regulations, the wage level can increase by up to 9 percent, depending on changes in the output index, without the wage-increase tax having to be paid. But there will be no possibility of that in the coming year for the enterprises in the grain industry.

This is because the value added is about three times the profit. In practice, the value added can be increased only by multiplying the profit. According to this, the profit would have to increase by three times 30 percent, that is 90 percent, in order for the wage level to rise by 9 percent without taxes. Taking into account the fixed or maximum prices, it is impossible to count on such a large increase in productivity.

Not just the financial regulations, but also the prices of produce have changed. The basis for price regulation was the year 1977. Disregarding minor official corrections--such as allowance for depreciation of storage capacity built by the government as a target investment--the profit expected in produce prices is the 1977 equipment inventory plus 4 percent of the total wages. In view of increased expenses over the past 3 years, the high commitment to equipment, the forced reduction in overhead costs in the years 1978-1979, and the limited possibilities for changing the production system, the new prices do not even yield enough to cover partial self-financing.

It is true that within the framework of the price system it has been possible to make the profitability of some domestic activities (milling, production of mixed feeds, etc.) approach that of exports, but in practice the price system had as its starting point not the realistic income needs of the enterprises in the grain industry, but the price levels of feeds and bakery products. (So, for example, in setting the retail prices of flour and white rice the aim was that there should be no need for retail price subsidies.)

With the discontinuation of the reserve fund for the food industry, the sensitivity of export output in the grain industry increased. Until the end of last year, 100 percent of the price difference in exports to ruble countries was covered by the reserve fund, and 95 percent of the profit from exports to nonruble countries was paid into this same fund. The loss resulting from the difference in price in food wheat used for animal feed was also covered. The reason for discontinuing the reserve fund was that profit resulting from the difference in prices from sales to countries with different economic systems could pay for the loss from reclassifying bread wheat as animal feed.

Results below or above the planned exports--which in the grain industry are determined by external factors--as well as changes in price levels can change the final outcome of an enterprise by several million forints. In practice, expansion of standing and working capital must be financed in the grain industry out of the development fund. But the sizes of these two main directions are not in harmony. In the grain industry the average inventory can vary from year to year by as much as 600,000 to 800,000 tons, with a value of 2 to 2.5 billion forints, because of grain production, time of marketing, possibilities for importing feeds, world-market prices, and domestic demand for feeds. Even one-third of this, 500 to 700 million forints, would involve such demands on working capital that even extraordinary work on the part of the enterprises would not be able to balance it, not even with intermediate-term credit, which in a particular year could reduce investment possibilities by 100 to 300 million forints. The large differences in the amounts available for investment make the investment activities of the enterprises in the grain industry very difficult and sometimes even haphazard.

VARIOUS SHORTAGES ENDANGER PROFITABLE CORN PRODUCTION

Budapest FIGYELO in Hungarian No 33, 1980 p 11

[Article: "Corn Cultivation: Conditions for Productivity"]

[Text] The Association of Hungarian Agricultural Sciences and the editors of FIGYELO arranged a round-table discussion of the possibilities and problems of expanding corn production. The experts agree that domestic corn production must be intensively expanded in order to feed 2 million head of cattle and 8 million pigs, and to exploit export possibilities economically. The results in 1979 were outstanding: the average production of corn per hectare was 5.4 [metric] tons, total production was 7.4 million tons. Domestic corn growers have been given the task of maintaining this level or increasing it without a decrease in productivity.

How Profitable?

Ecological conditions in Hungary are favorable for corn cultivation. The question is just this: What conditions are necessary so that the large agricultural operations can achieve higher average production and greater total production than today, without impairing economic efficiency? That is, so that the yield will increase faster than expenses. This has been successful in recent years under the Babolnai Industry-type Corn Production System (IKR), whose 235 members raise corn on about 240,000 hectares.

Growth of Profitability of Corn Production per Hectare in the IKR
(average of 235 members)

	1977	1978	1979
Average production (tons	5.52	6.02	6.31
Value of produce (forints)	14,113	16,066	16,706
Expense of production (forints)	12,337	13,554	13,665
Net income (forints)	1,776	2,512	3,041

Under this same IKR system it required a production of 4.5 tons to cover the cost of growing corn on 1 hectare in 1977 and 4.9 tons in 1978 and 1979. This year it is expected to go up to 5.1 tons. This size average production must be achieved so that the operations will at least break even and not have to pay for their corn. In view of the ever-increasing costs of production, profitable expansion of production will require new initiatives and the creation of conditions that have hitherto been lacking.

In recent years for example, soil analysis has developed greatly. It is today no problem for the operations to determine the needs of their soil for nutrients. Thus they could put precisely the amount and composition of nutrients needed on their soil, if industry and commerce could always fill their orders. But this is often not the case, so they often use whatever fertilizer happens to be available. In the IKR last fall they wanted to fertilize with calcium and phosphorus, but at that time those minerals could not be obtained, so they were not put onto the soil till this spring. But that does not have the same value as fertilizing in the fall, because the harrowing which is required after it, dries out the soil. This results in a poor bed for the seeds.

These technological deficiencies and forced solutions are accompanied by serious economic consequences. Efficient use of ever more costly fertilizers and chemicals for protecting plants can only be guaranteed if they can be applied at the appropriate time, and in the appropriate amounts and composition. Fertilizers are becoming a more and more significant expense factor. For example, in the IKR they amount to 25 to 30 percent of production expenses.

Efficient use of fertilizer is also impaired by a lack of appropriate spreading machines. In the IKR, 480 kilograms of nutrients per hectare were applied to the soil, of which about half is utilized. The inefficient fertilizer-spreading machine has been improved by experts employed by the system, and they work with good efficiency. However, the Agricultural Machinery Trust will not undertake production of the modified machine, and is only willing to deliver the old type, which the operators could modify if they wanted to. This is an extra cost of production and is hardly the best way to improve productivity.

Good sowing seed is also a condition for good production. In recent years the selection of corn seed has expanded rapidly; the most modern hybrids have quickly appeared in Hungary too. At present the operators of 1.5 million hectares of corn-producing farms can choose from among 48 kinds of hybrids. According to the producers, however, the Hungarian regulations are too lax, and they permit a relatively high proportion of imperfect seeds, as a result of which reason the rate of sprouting in the field differs significantly from the results of laboratory tests (15 to 20 percent lower).

Conditions for efficient corn production also include reliable and energy-saving machines for tilling. In Hungary, cost-saving procedures for tilling the soil cannot yet be implemented for lack of suitable machines. But the large-capacity tractors can pull several tilling machines at once. With such so-called joined machines, energy can be saved and the work of tilling can be accomplished faster. According to the factories which manufacture agricultural machines, there is no demand for joined machines, and therefore they do not make any.

The reliability of the machines on hand depends of course not only on their technical level, but on the availability of spare parts. Certain machines can place their operators in a difficult situation when availability of spare parts is poor. So they may prefer to buy less modern machines with smaller capacity, for which spare parts are available, than those which, though modern, can remain idle for weeks waiting for spare parts.

Harvesting and Storage

At present a major portion of the corn harvest is ground and dried with drying machines powered by oil. But this method--if the operators intend to use the corn for feeding their own animals and not for sale--is extremely inefficient. Because of the small capacity of the drying machines, the operators generally speed up the drying process. But drying at too high a temperature destroys some of the nutrients, lessening the food value of the corn. Such over-dried corn cannot be utilized as well by the animals.

According to statistics compiled by the Grain Trust, about one-third of the corn crop is utilized in the operations involved in direct feeding of animals, and the remaining two-thirds enters the commercial market. As a first step, it would be expedient for the farms to preserve and store at least their cattle fodder moist and not dry it. It will still be necessary to dry it for use in production of feeds and for commercial sale, but instead of hot-air drying, which requires much energy, the method of drying in cold air--the old method used in small farms--could be implemented. It is true that by this method drying takes longer, but then the food value of the corn does not suffer.

PREPARATIONS NECESSARY FOR 1981 PLAN REVIEWED

Bucharest REVISTA ECONOMICA in Romanian No 32,8 Aug 80 pp 7-8

[Article by Vasile Parascan: "The Leap to a New Quality Involves New Requirements in Plan Preparation"]

[Text] Recently, there was a meeting of the Political Executive Committee of the Romanian Communist Party's Central Committee, the Permanent Bureau of the Supreme Council of Economic and Social Development and the Government of the Socialist Republic of Romania which discussed and approved the Report Regarding the Sole National Economic-Social Development Plan for the country in 1981. A fundamental goal established at this meeting for the ministries, centrals, all enterprises and local party and state organs is to take energetic, firm measures to prepare in advance and under the best possible conditions for the exemplary fulfillment of all plan indicators and goals in the coming year.

In this context, there is special significance in the advance provision of a technical-material base for the plan, a decisive condition for achieving planned production and investment projects and providing goods for the market, and for fulfilling provisions for exports. The experience of recent years clearly shows how important it is for each enterprise to have all problems clarified prior to the beginning of the plan period regarding the sale of production and supplies, to know in detail the requirements and possibilities of the partners with which they will deal and, especially, to perfect these dealings through economic contracts.

In order to ensure the best possible conditions for fulfilling plan tasks, priority attention must be given to achieving the planned production in the primary production sectors for basic raw materials that provide the resources for the intermediary and final processing phases for these products. To this end, it is first of all necessary to carry out the intensive geologic projects program, which represents a significant increase compared to 1980 achievements, especially in the fields of hydrocarbons, coal and nonferrous ores. Bringing about the increases in the geological reserves outlined in the plan tasks represents one of the decisive elements for the development of mining production.

In this field, first priority goes to intensifying activities for the on-time completion of projects and the start-up of new production facilities for lignite in the Oltenia mining basin (Tismana II, Rosia de Jiu and Pesteana Jiet-Sud) through the better organization of strip-mining projects and the improvement of the degree of use of excavation equipment. Decisively depending upon these measures is the production of lignite, whose percentage in the structure of energy sources is noticeably increasing. It is enough for us to point out that approximately 60 percent of the electricity produced in the country comes from the use of coal and hydro-electrical power in order to show the substantial changes that are occurring in this field. At the same level of importance we also find increases in the production of non-ferrous ores, copper, zinc and lead. In this area in recent times world prices have shown a tendency for increases, so that the complete fulfillment of production programs for these ores also represents great significance from the point of view of providing certain important hard currency savings.

All of the branches have especially important tasks with regards to ensuring a energy base and rationally using all categories of energy sources. Without a doubt, first place goes to the task of reducing the consumption of fuels, combustibles and energy. It must be said that the measures to reduce consumption imposed not merely for economic reasons, but because of the trend of continuing increases in the purchase prices for oil on the world market and the difficulties in obtaining oil constitute a key point in the 1981 plan, and each economic unit must rigorously adhere to the amounts allocated to it. Unfortunately, this year's experience shows us that many enterprises were caught unprepared to meet the tasks of reducing consumption, and they did not take the necessary measures in time. For that reason, we feel that it is worthwhile to emphasize several of the concerns that must be considered by the enterprises in preparing for next year's plan from an energy point fo view:

-- updating all products and energy-intensive technologies and limiting production to the strictly necessary amount;

-- scheduling the judicious use of heating furnaces (for rolling, forging and so forth), with periodic shutdowns when the volume of work does not justifiy continuous operation;

-- ordering and installing heat and air preheating recovery units. In 1981. we will have to recover over 20 percent more of recoverable energy resources than in 1980. What is especially important is that approximately 60 percent of this will have to be used in 1981 in units other than where it originated, which requires that we now draw up the solutions, designs and projects that will be required;

-- in order to identify the real level of energy resource use it is necessary to use or, as the case may be, to draw up an energy use review for each consumer installation, on the basis of which to define the measures to eliminate any waste;

-- energy conservation measures are necessary in the field of transportation by strictly adhering to both optimization schedules and the broad scale use of tractor-trailer tractors and full-load round-trips;

-- in the field of electricity production and transmission, the levels of consumption in their own technologies and losses in their networks will be substantially reduced, so as to represent no more than six and five percent, respectively, of the total;

-- expanding on a broad scale the use of new energy sources and, above all, energy from thermal waters, so as to make a contribution to the primary energy balance of over 300,000 tcc next year. Another important source is micro-hydroelectrical power centers built on interior rivers which could noticeably reduce the consumption of electricity produced from fuelds.

Several problems require attention with regards to the timely preparation of conditions for providing the economy with metals. First of all, it is especially important to concentrate all efforts to reduce the length of the timeframe for attaining projected parameters at the new heavy plate rolling mill at the Galati Steel Combine, whose contribution to the total balance of metals is decisive in ensuring the necessary amount slated to go for production in the machine building industry. In all the metallurgical units, and especially at the Special Steels Combine in Tirgoviste, they are still facing problems this year with regards to the accentuated increase in the production of certain types of metals that put raw materials to higher use and the reduction of imports. We are talking about production increases in stainless and refractory steel plate, where production must be double compared to this year, with production increases in electrotechnical plate steel, forged bars and blocks of tool steel, calibarated steel and others whose production directly conditions the provision of a material base of certain important sectors of the national economy.

Similarly, it is worth noting that overall ferrous metallurgy will have to obtain a metal output index of 80 to 85 percent, to which end the Ministry of the Metallurgical Industry must now organized detailed analyses in every combine and come up with output indices in accordance with the measures and the existing specific conditions in each unit.

Another element of special significance in the overall preparations for the 1981 plan is ensuring the conditions for the maximum recovery and use of all categories of reuseable material resources. As is stressed in party documents, these resources must be used to a greater degree in ensuring the necessary amount of raw materials, for some resources at the rate of 40 to 50 percent and even more. It should be remembered that next year recovered ferrous metals will reach the level of nearly 7.7 million tons, or over 40 percent in the production of steel. Increased tasks are also foreseen for nonferrous metals, totalling 20 to 25 percent of the metals recovered in the total production, for wood materials, for textiles and so forth. It must be especially pointed out that all measures must be ensured to recover approximately 300,000 tons of paper and cardboard, which will be substituted for important quantities of wood materials and which will condition to an important degree the provision of resources slated for different categories of paper, cardboard and items made from these products.

There must be an intensification and completion in the shortest possible time of projects regarding technologies for using certain reuseable resources that currently are not put to use. In each branch and in nearly every enterprise there are these types of problems and there is also the technical and organizational potential to solve them. We will refer to only some of these: tinplate for canning, red mud with iron content from the production of aluminum, useful elements from light bulbs, fluorescent light bulbs, electronic tubes, electric batteries, bakelite from various used items, different types of residual waters, gypsum, textile waste from blended fibers and numerous others that constitute a potential whose use would allow the making of products worth billions of lei, without calling upon any new raw materials.

In this field of reuseable resources, we must work so that right from the second quarter of this year, according to the established tasks, we can increase the volume of collections beyong the initial level in the plan with special accent on ferrous metals, nonferrous metals, paper and rubber. With regards to rubber, it must be stressed that all categories and sizes of tires must be recovered when they reach the limit of use for repairing or recapping. To this end, special attention should be given to the on-time completion of the new recapping facilities slated to be built both through the development of existing units in Bucharest, Tirgu Frumos and Iasi and through new units planned to be built in Tirgu Jiu, Marginea-Timisoara, Constanta and Zalau. The Ministry of the Chemical Industry must provide the on-time production of all equipment and assemble and install it in order to achieve, in this manner, the planned resources and make important savings in the quantity of new tires.

Within the framework of preparing the 1981 plan's material base, much attention must be given to drawing up programs and creating conditions for effecting repair and maintenance projects upon which the optimum use of production facilities and the achievement of product resources in the

plan depend. As is known, a series of deficiencies continued this year in ensuring planned repairs because of insufficient preparation and the failure to obtain spares and other items. This led to production losses, especially in carbon black, polyisoprenic rubber, synthesized ammonia, cement, fabrics and so forth. The principal objective of activities in this field must be the establishment of repair periods and length of downtime for each installation and piece of equipment and the determination of the necessary numbers of spare parts and, first of all, those that can be obtained through reconditioning or from our own production, keeping in mind that the repair schedule influences the rhythm of production, the month-to-month scheduling of production and, as a result, the deliveries that will be made through economic contracts.

Special attention must be given to a thorough preparation for investment projects by ensuring the necessary documentation and equipment, creating the conditions at all work sites and starting up new objectives and facilities on-schedule. As is known, in the wake of the measures taken construction and assembly efforts must be concentrated at a number of work sites and industrial complexes where all the conditions must be created to complete the projects in the shortest possible time. In this direction, we must especially keep in mind the following principal tasks:

-- bring up to date right during this quarter the construction documentation for those projects still be completed after 1980, using designs with the most efficient construction solutions;

-- improving construction and assembly contracts by immediately establishing contracts between the user and builder and drawing up a monthly and quarterly schedule for completing projects;

-- drawing up and presenting orders for approval for the projects that are to be started in 1981;

-- establishing the volume of equipment by each ministry with the Ministry of the Machine Building Industry and with the other producer ministries that is to be delivered to each project and contracting for this equipment for timeframes correlated with the assembly schedule, giving priority coverage to the necessary amount for the development of production of fuels and energy.

All these measures are designed to lead in the end to the achievement of planned production volumes at the new facilities, an aspect of special importance in respecting the initially established material balance throughout the plan.

The entire process of preparing for ensuring the material base of the 1981 plan must be finalized through the complete contracting of production both for domestic use and exports and the provision of the appropriate technical-material supplies in all enterprises and through the strict

adherence to the approved norms of consumption in all production units. Once the general framework of the plan is established, its is absolutely necessary to immediately move to clarifying all problems and to develop the quotas and forward assignments so that by the end of the current quarter all contracts are concluded. One of the most damaging phenomena in this activity is passivity, waiting for problems to be solved from above through administrative acts. And, as is known, one of the essential characteristics of self-administration and self-management is the enterprises' obligation to determine their own production profile, by types, in accordance with the real needs of the economy, to contact and known suppliers of raw materials and to specify all the details concerning the characteristics of the goods sold and supplied. And, these things are very little carried out, with many enterprises waiting for assignments to resolve their sales and, in this manner, they could require the consumption of certain products that the economy needs. That is why in the current stage it is necessary for each central and enterprise to organize reciprocal contracting activities between suppliers and users and to clarify all aspects prior to finalizing economic contracts. The manner in which we work now, in this stage, will decisively condition the beginning of the plan next year, which is, at the same time, the first year of the new 1981-1985 five year plan.

ROMANIA

IRRIGATION SYSTEMS TO BE EXTENDED, MODERNIZED

Bucharest REVISTA ECONOMICA in Romanian No 32,8 Aug 80 pp 12-13

[Article by Dr Petru Pantiru of the University of Galati: "The Program for Extending Irrigation - A Component of a New Revolution in Agriculture"]

[Text] Reflecting the economic-social relations in our country, the agrarian policy of our party and state established the major objectives in each stage of development, calling for the progress and modernization of agriculture. Among these objectives, a decisive place is held by the extension of irrigation, as a basic factor of increasing the production and efficiency of agriculture. The importance and need the carry out an irrigation program rest in the fact that together with the other factors of production they must ensure the growth of the efficiency of the land to the maximum limits of the possibilities offered by contemporary science and technology and the pedoclimatic conditions of our country. Currently, comparing the results obtained by our country's agriculture with those in countries that have large irrigated areas shows that for corn, a crop that uses irrigation to the greatest degree, the average production per hectar in 1977 (the last year for which the statistical yearbook in 1979 published comparative data) was 5,290 kg in France, 6,570 kg in Italy, 5,700 in the United States, 4,230 kg in Spain and 3,040 kg in Romania.

The scope of land improvement projects recorded a decisive turning point right after the Ninth Congress of the Romanian Communist Party. On the basis of a rigorously scientific analysis, the Congress showed the remarkable economic potential of Romanian agriculture, stipulating the necessary ways and means for its development, including the significant role that must be played by irrigation. In this regard, clear and concrete measures were established referring to: increasing the funds for land projects; extending these projects by hydrographic basins and territorial-administrative units; developing the industrial sectors that supply the equipment necessary for irrigation; and, granting assistance (financial and technical) to the agricultural cooperatives for carrying out local projects and for modernizing existing ones. At the same time, our party has combated firmly certain concepts from that past era, according to which irrigation cannot be efficient, concepts that actually slowed the development of these projects in our country for a good period of time.

The transition to a qualitatively new stage in the development of our society, marked by the Tenth Party Congress, required the establishment of new tasks in the field of water use and the extension of projects to improve and conserve land resources in view of developing and modernizing agriculture in close connection with the rates of growth of the national economy and the requirements of social life. Under the new conditions, the programs previously drawn up regarding the management of water and the extension of irrigation no longer corresponded to the objectives of the new stage. As a result, on the basis of the decisions of the Tenth Congress, there was a move to drawing up the "National Program Regarding the Rational Management of Water Resources, the Extension of Irrigation Projects and the Combating of Soil Erosion During the 1971-1975 Period and the General Provisions Until 1980."

The later guidelines of the party leadership, the directives issued by its secretary general and the evaluations made of the objectives contained in earlier programs, as well as the furthering of studies in this field in close correlation with the requirements of creating a multilaterally developed socialist society, created the premises for drawing up, on the basis of the decisions of the 11th Party Congress, the "National Long-Term Program for the Management of Hydrographic Basins in the Socialist Republic of Romania." Conceived from a new viewpoint, this program contains the group of projects necessary for the management and complex use of water, such as: the management of the entire hydrographic network; the regularization of all water courses; the creation of an important number of holding basins and lakes; the management of the entire economically irrigable potential of the country; the prevention and combating of floods, pollution and soil erosion; the development of interior navigation; the growth of fish production; the full use of the country's hydrographic potential and so forth. The national program calls for providing, by the year 2000, the water necessary for the development of the entire economically irrigable potential (of 5.3 million hectares) and even certain supplementary areas of nearly two million hectares, under conditions where the extension of irrigation will prove necessary and opportune.

During the 1950 to 1979 period, irrigation projects were in a continually ascending, but not uniform evolution in its rate and degree of modernization (see Table No 1).

From an analysis of the carrying out of the process of managing land for irrigation we discern two periods. The nature of the first stage (1950 to 1965) is expressed in the fact that the rate of extending irrigation was slow, with this due to both the more reduced economic possibilities of the country and specific conditions in the period of socialist transformation of agriculture and the fact that there was not a full understanding during that time of the importance of the irrigation factor for the intensification and modernization of agriculture. Further, even some initial provisions referring to the development of irrigation projects were cancelled in the

1961 to 1965 period. The moment marked by the historic Ninth Congress is also reflected in the fact that in the 1966-1970 five year plan the developed surface area was two times greater than that existing at the end of 1965, while in the next five year plan (1971-1975) these projects were extended by another approximately 760,000 hectares, or over 3.4 times more than the entire area that had been developed up to 1965. The intense rate of carrying out irrigation projects from 1965 to the present has resulted, at the end of 1979, in the fact that we have available a developed area of over two million hectares, which represents 13.54 percent of the agricultural area of the country and 38.13 percent of the economically irrigable potential.

Table No 1
The Evolution of the Agricultural Area Developed for Irrigation

Year	Agricultural Area Developed for Irrigation (Thousands Hectares)	Percent of Developed Area In Total Agricultural Area	Percent of Developed Area in Total Area of Irrigable Potential
1950	42.5	0.29	0.80
1955	93.1	0.65	1.75
1961	184.6	1.27	3.44
1965	222.6	1.50	4.15
1970	664.6	4.45	12.40
1975	1,424.2	9.52	26.55
1978	1,822.8	12.18	34.39
1979	2,020.8	13.54	38.13

Also in this period (1966-1979) there were important changes with regards to the modernization of irrigation projects, as well as in the structure of crops in accordance with the extension of irrigation. In this regard, we should mention: the elimination of irrigation via surface draining in those areas where this method does not give the best results and the use of sprinklers instead; the introduction and expansion of the type of irrigation using pressurized pipes; the concentration of irrigated surfaces in large systems with a centralized water supply; the expansion of the use of crops having the greatest demand for water; the establishment of certain crop rotation schedules designed for irrigated lands; and, the diversification of the structure of crops and the adaptation of these crops to the needs of society.

The 12th Party Congress marked a completely new stage, completely different from the previous periods, in the field of developing and modernizing agriculture. The defining characteristic of the development strategy of this branch in the period to follow was the carrying out of a profound

agrarian revolution that included both the development and modernization of the technical-material base and the furthering of the process of organizing production. In our party's view, the achievement in practice of these two facets at the current level of creating a multilaterally developed socialist society presupposes: the rational use of the entire land fund; the conclusion of the process of regionalizing crops and establishing a crop rotation schedule; the complex mechanization of agricultural projects and the chemicalization of production; the full modernization of wine and fruit growing; the continued growth of the numbers of animals and the improvement of animal stocks; and, the radical solution of the problem of fodder.

Understanding the fact that the demand for agricultural products is becoming ever greater (as a result of the development of the entire economy, of providing an ever higher standard of living, of the growth of the population and of export demands) and under conditions where the arable land is and remains, naturally, limited, irrigation becomes an element of great significance for the development of agriculture in the context of achieving the goals of the agrarian revolution. Specifically, irrigation ensures increasing the production capacity of the land, brings about substantial changes in the structure of crops, changes the profile of agricultural zones, influences the development of new brances of an industrial nature and contributes to the integration of agriculture into industrial activities and to the judicious distribution of the forces of production throughout the country, thus being a factor in the elimination of differences between the country's counties. To this end, in the group of tasks established by the 12th Congress of the party a special program was drawn up for the 1981-1985 period regarding the development of irrigation systems and land improvement. In this stage, it calls for the additional development of 700,000 to one million hectares so that by the end of 1985 the total area developed will reach approximately four million hectares, which will represent 75 percent of the economically irrigable potential.

Concomitant with the expasion of the area, important changes in the field of construction technologies and the use of developed areas are also called for in the documents of the Congress and in the special program. Thus, from the point of view of water supply and differing from the systems built in the past, 80 percent of the new lands will have existing water basins as their source of water plus those that will be built in accordance with the objectives of the national long-term program for the management of hydrographic basins.

In this stage, important water storage basins will be put into operation in the Olt, Buzau, Prut, Somes, Ialomita and Siret basins, with the result being that in the future five year plan the largest irrigated areas will be developed in these basins. From an administrative-territorial point of view, the new systems will be located in Ilfov, Galati, Ialomita, Buzau,

Dolj, Prahova, Arges and Botosani Counties so that agriculture will substantially contribute to the growth of total production per inhabitant in the economy of these counties.

Of the newly developed land areas, approximately 75 percent will belong to the agricultural production cooperatives, with this involving especially important tasks for the unique state and cooperatist agro-industrial councils which have full responsibility regarding providing the conditions necessary for the carrying out of irrigation projects and the rational and efficient exploitation of these projects. These organizations also have considerable responsibility with regards to carrying out local projects that will extend to an additional 20,000 hectares in the next five year plan. In order to supply this area, they will use as a water source the water supply basins that result from the development of approximately 400 kilometers of natural valleys.

The agrarian revolution will also mark a qualitatively superior stage in the field of irrigated agriculture efficiency. Moreover, the new developments are conceived in an improved way that takes into consideration advanced construction solutions and technologies that will permit the reduction of material, energy and manpower consumption. Within the framework of the complex group of solutions of a technical nature, an important role in the construction phase is played by the spread of the type of project using a slow canal network and a buried pipe distribution network, a solution capable of ensuring the reduction to a minimum of the land area occupied by the projects and the losses of water during use, as well as the realization of significant material savings. Similarly, the use of hydrant pieces and accessories in the pipe network will lead to a reduced consumption of metal. The introduction of certain improved procedures for the waterproofing of irrigation canals will reduce the consumption of metal stemming from pump replacement. We also have in mind the diversification and improvement of installations for the mechanization of water application operations and the growth of the percentage of self-deploying equipment, which will also ensure the improvement of the quality of sprinklers, as well as decrease the use of manpower in exploiting the land. The movement of water through gravity-flow channels and low-height lift pumps (compared to the current 66 meters, the pumping height in the new systems will only be 38 meters) will have implications for the noticeable reduction of energy comsumption in the use of the projects. The spread of the furrow method of irrigation wherever it is possible, accompanied by the possibility of also using sprinklers in those projects in the case of crops planted in close rows, constitute still another factor for making irrigation efficient.

Another important direction for action in transiting to a higher quality in the field of irrigation efficiency is the complete use of the area and the correct application of waters and other production technologies in order to obtain increased efficiency per hectare. In this regard, the

secretary general of the party emphasized at the Working Conference of the Central Committee of the Romanian Communist Party in February of this year: "We are making a great financial effort in this area; each hectare that is irrigated costs us, on the average, 20,000 lei. For that reason, it is inadmissible for us to use only partially those areas that we have irrigated."

Beginning with the major objectives of the agrarian revolution, the role of agriculture in the development of the country and the direct implications of these activities, the problem of the efficiency of irrigation must be considered, in our opinion, in a broader context, keeping in mind two large aspects: a) increasing the net income per hectare on the basis of achieving large production for each crop and of establishing certain efficient structures on the perimeter of the project or in specialized areas; b) ensuring to a fuller degree the social needs for different agricultural products as a result of the increased demands of industry, other sub-branches in agriculture, supplying the populace and creating amounts of products for export.

In close connection with this manner of viewing the efficiency of irrigation activities, the problem is also raised regarding the elements that must be taken into consideration when we propose figuring efficiency. We feel that in the complete evaluation of the efficiency of irrigated agriculture we must, perhaps more than in any other branch, keep in mind the cumulative efficiency of irrigation activities. This involves also extending the analysis to those branches and sub-branches that use the raw materials from agriculture (raw materials from irrigated crops), to the export of agricultural products and, implicitly, to the expenditures (evaluated in other exported products and in hard currency) that would be made if these products were imported.

Along the same lines, another element in evaluating the efficiency is the length of the timeframe being analyzed. In our opinion, if this is limited to a year it cannot lead to the formulation of certain telling conclusions. Consequently, the efficiency of the projects should be determined for the entire period of operation of the irrigation system in order to see to what degree the investments can be recoverd at the level of the unique agro-industrial council, simultaneously with the use of those crop structures that meet the demands made by society.

Even the experience to date shows us that the large systems, located for the most part on the land of agricultural units or that of a small number of enterprises, have provided large production per hectare. This is also explained, to a good measure, by the fact that only in this manner can there be a rational mixing of crops, keeping in mind natural, economic and social factors. In this sense, the results of the two irrigation systems in Galati County are graphic.

Table No 2
The Value of Production Achieved on Irrigated Lands

Farm	Developed Land Systems (Hectares)			Production Achieved (Lei/Hectare)		
	1976	1977	1978	1976	1977	1978
Barbosi	3,155	3,155	3,155	8,266	10,666	7,845
Tecuci	14,081	14,327	13.736	4,784	10,492	11,109

As shown in Table No 2, the average total production obtained per irrigated hectare was over 11,000 lei, with reserves still existing for its improvement. The formation of councils and the creation within these of unique sectors for mechanization, chemicalization and water improvements constitute new premises in the growth of production. These sectors have the task of providing the administration and maintenance of all systems under good conditions, of fully using all the developed land with increased efficiency and of applying the appropriate technologies and the entire complex of factors for increasing production.

A decisive direction for increasing economic efficiency, emphasized in the documents of the 12th Party Congress, is the development of scientific research. Thus, the Program-Directive for Scientific Research, Technological Development and the Introduction of Technical Progress establishes as objectives for study in the field of irrigation: the adaptation of certain solutions that will lead to the reduction of water consumption; the production of certain watering installations and equipment having high productivity and whose use will permit the mechanization of watering, regardless of the size and state of development of the crops; the use of certain improved types of irrigation and equipment with the possibility of applying certain norms for variable watering corresponding to the requirements of the crops at any given moment; the reduction of the use of materials and energy; and, the achievement of certain hybrids having an increased ability to use useful substances contained in chemical fertilizers.

Along with the further use of science and technology in economic processes and the development and modernization of the technical base, an ever greater role is played by the specialists and all workers, concomitant with the increased responsibilities of each worker in carrying out his tasks on-time and in the best possible conditions.

Working in the spirit of the 12th Congress documents and the secretary general's directives, agricultural workers and all our people have the guarantee that the objective of carrying out a profound agrarian revolution can be fully realized, placing this basic branch of the economy at the highest points of economic and social progress.

OLTENIA COAL BASIN OPERATIONS: PROBLEMS, SOLUTIONS VIEWED

Bucharest REVISTA ECONOMICA in Romanian 1, 15 Aug 80

[Article by Vasile Boescu and Bogdan Padure]

[No 31, 1 Aug 80 pp 9-10, 17]

[Text] The discovery and utilization of raw material and energy resources are one of the cardinal problems of our economic development. On one hand, this is due to the dizzy rise in the prices of raw materials by the large foreign suppliers and, on the other, as a result of restricting the volume of reserves available on the world level. That is why the problem of intensifying geological research activity for the discovery of new resources as well as the utilization of raw material and energy resources at a high level has been posed as a major task facing the specialists and all workers by the party and state leadership.

In this context we also have the operation of existing lignite reserves in the Oltenia coal basin, as an available resource for the production of electric energy in the country. For utilization of them, two of the country's largest thermal electric power centrals--in Rovinari and Turceni--also have been set up in the center for coal operations in this zone. But Oltenia's lignite is a fuel for the other large thermal electric power centrals, too, and for supplying the population, so that the uninterrupted increase in production has become a major goal.

Fulfillment of these tasks requires the moblization of all technical and human potential in this coal basin and organization of production in such a way so that the plan forecosts--the quantitative and qualitative ones--for coal extraction and for the investments for placing the new capacities into operation can be fulfilled in an exemplary way. From this viewpoint how do matters stand with the Oltenia mining Combine?

Steady Plan Fulfillment and Steady Delivery of Coal to the Beneficiary

The characteristic of most Oltenia operations is surface coal extraction in large pits, although underground workings also exist.

Depending on this specific, broad suppliers have been provided with the necessary means of production and modern operation and utilization technologies have been put into practice. On this base production recorded marked increases, particularly this year. Whereas 60,000 tons of coal per day were being extracted in 1979 (under conditions where the Beterega pit also is in production). production this year rose to 80,000 tons per day, without placing new capacities into operation. The Oltenia operations in this way are in the forefront of Romania's coal production, with more than 32 million tons to be extracted and delivered to the electric centrals this year.

A number of enterprises of the big combine month after month are steadily fulfilling the plan provisions and, on this base, they are honoring the economic contracts concluded. Among them are the Urdari, Motru and Lupoaia mining enterprises. In Urdari, for example, due to the superior organization of work, they have reached 84,000 tons per year in productivity per man and position; in the other enterprises, as well, through the good use of equipment for driving the internal transport, between 15,000-25,000 tons of coal are being produced daily. What is more, the favorable geological conditions in these operations also permit the quality of the coal to approach and sometimes even better the forecasts. Also, the thermal electric power centrals being supplied with lignite from these operations (Isalnita, Turceni, Doicesti and Oradea)annually are paying large amounts as rebates for the high quality of the coal received compared with the contract provisions. The units mentioned have also obtained good results in raising the qualification of the work force and utilizing the excavators, underground mechanized means (particularly the combines) and tip trucks with high output; at the same time, we should mention the concern of the leadership cadres with providing new capacities and work fronts on time, ones which permit the continued rise in coal production.

However, following the diagram of production by combine and for each enterprise and operation, we find that the fulfillments do not rise to the level of plan requirements: Up to the middle of July nearly 6 million tons of coal have been recorded as back production, while the lags are much greater for deliveries to beneficiaries (it also is a matter of back quantities from prior years). At the Jilt enterprise only around 30 percent of the plan forecasts were fulfilled in the 1 January-15 July period; for Rosia it was 26 percent and at Rovinari it was 70 percent. Such a situation has led and is leading to upsets in the activity of the beneficiaries, that is, the thermal electric power centrals. Thus, at the Rovinari thermal electric power central the lack of supply, added to which is also the inferior quality of the coal delivered, have meant that a large portion of the energy production plan is not being fulfilled for the first half of the year. And this is under conditions in which the black oil consumption exceeded forecasts. And large lags in supplying coal have been recorded for other beneficiaries.

The reasons which have led and are leading to the recording of lags in the plan and contracts are both of a subjective as well as objective nature and are not new.

As Comrade Nicolae Ceausescu pointed out at the RCP Central Committee working meeting in May, "The failure to fulfill the coal plan is the result of lacks in the appropriate organization for carrying out investments and continuation of the negative state of affairs, particularly in Oltenia, in creating the necessary base for assuring coal production achievement. Very serious and immediate measures are required to solve this problem effectively in Oltenia. We will not be able to supplement the failure to produce 6 million tons of coal in Gorj with the production of the other mines. For that reason, without neglecting the opening of new mines, the main attention should be concentrated on the efforts which must be made in addition and, in this framework, let us also see what must be done to help this county, including with a work force, in order to be able to extract the coal we need. The failure to fulfill this year's plan involves great consequences for next year and for the coming period in general."

Why the Delays in Placing New Extraction Capacities Into Operation?

One of the main shortcomings hindering the achievement of coal production in the Oltenia basin at the amounts planned is the lags in placing large capacities into operation, particularly through the stripping of land areas in whose veins the coal is found. Whereas precisely the forecasts for excavation would have been fulfilled in the last 4 years, an active coal reserve of nearly 25 million tons, equal to the current need, would have been assured. The problem in itself, among other things, involves a number of aspects which should be remembered because the measures which have been taken and which will be taken to contribute to speeding up the rate at which the new production capacities are placed into operation.

Above all it is a matter of the need to respect the provision that the stripping projects be carried out with proper equipment--tip trucks and multi-bucket excavators. The lack of these in some zones, particularly the hilly zones (Tismama I, Rovinari East and so forth)has brought the utilization of excavators with rotors, a fact which has led to lower productivity, the failure to do work on slopes, frequent defects in the equipment and carrying out daily excavation programs in proportions below the tasks and so forth. Thus, the result is the objective need that appropriate equipment be programed in accordance with the state of the land so that the stripping forecasts can be carried out on time and even ahead of schedule if possible. At the same time, it is necessary for the suppliers who have contracts with the mining units for this equipment to give them priority in manufacture and immediately recover the lags in delivery.

Taking into account the specific conditions of the zone, it also was necessary for the drainage projects for the swamps and very damp places to be carried out at least 1-2 years prior to the point of transition to stripping and the actual exploitation of the coal veins. However, in practice, in many cases coal exploitation has been carried out together with the drainage and stripping work, ignoring certain technological rules required under such conditions.

If it is true that this matter is due to start of mining jobs depending on certain urgent needs, then it is just as true that sometimes the failure to start on time has been the result of a lack of preparation and well-founded, timely organization of investments. It is certain that such a method of work has had and does have negative effect on a rational utilization of the technical base and work force in assuring the exploitation from for the future . In order to avoid such shortcomings in the new mines, greater attention is needed in establishing the order to start jobs, in organizing and balancing all activity so that the urgent jobs can be carried out better coordinated with the start of the future jobs.

In the same framework one may also speak of the failure to build access roads and traffic roads, the finishing of which would have been needed earlier in order for the heavy transport equipment to be operated intensively and extensively, even under conditions of the most varied temperatures to which coal mining subjects it. This explains the fact that some exploitation and transport aggregates get stuck in the mud in some pits, a fact which has made them inactive for a prolonged period or which has led to the deterioration of some of them much before they have fulfilled the planned operating programs.

In the end, we cannot help but recall here that in some cases large amounts of investment capital havebeen spent while a good portion of the work force and of the equipment has been affected by some stripping projects because, in the end, the layer of coal as well as the quality of it are below estimates and, clearly, below the level of efficiency anticipated. Of course, in any research there is a certain risk factor, yet the good results obtained in many cases show that it is possible for the geologists to draw up maps, diagrams and estimates which are closer to reality in many cases, on the basis of much more thorough studies and research which are substantiated more strictly.

In conformity with the tasks given in the party documents, a number of measures have been taken to improve the situation in this area. Thus, starting in July large-capacity means of transport, accompanied by qualified drivers, by mobile workshops for intervention and qualified cadres arrived from all over the country; national youth job sites were also organized and so forth. The thousands of people arriving in the Gorj zone and the hundreds of pieces of large-capacity equipment will aid the combine's enterprises for a certain period of time, primarily in doing the stripping jobs, to speed up the start of some main coal extraction capacities into operation, the extraction and transport of as large a quantity of coal as possible to the thermal electric power centrals in the zone and the warehouses. In order for this action to give the best possible results, it is necessary for the entire technical apparatus of the combine and the enterprises to be present at all work points, assuring the necessary technical assistance and contributing promptly to the application of the most efficient organizational and technological measures.

The construction of warehouses to stock coal both for suppliers as well as beneficiaries is a well-initiated measure which should be continued. The advantages obtained are substantial if we bear in mind that conditions are created in this way for the superior drying of coal and for raising quality, its content in calories through sorting and mixing. At the same time, taking into account their capacity, action should be taken urgently to fill them with quality coal. On this basis the buffer stock of coal, which should increase more than 1.5-2 million tons, will mean that the thermal electric power centrals should have a certain independence from the suppliers, avoiding critical supply situations. At the same time, the buffer stock will assure continuity in the supply with coal in the winter period, when the weather is unfavorable for various operations--excavation, transport from the pits to the warehouses and so forth.

More attention should be given to the way in which the stripping work is done. In this connection the problem is posed of selecting fertile earth and storing of it separately. Action should be taken with more responsibility in this area to avoid situations where the same earth excavated was stored in one spot, without taking into account that a good portion of it was fertile. For this reason, following the work after coal extraction, when the holes were covered and the land prepared to be returned to agriculture, the ground could only be utilized for agriculture after a period of several years, with costly fertilization work needed. Also, the action of returning land from which coal was extracted for agriculture must be intensified very much, since until now only one-tenth of it has been prepared to be cultivated.

A thorough analysis of the measures specified for investment activity and prompt finalization of them and follow-up on the basis of a schedule of results, taking into account the new conditions created (aid with the work force and equipment), that a large volume of lags to be recouped and assures a solid base for 1981 production, when it will be necessary to extract a much greater quantity of coal.

[No 33, 15 Aug 80 pp 5-6]

[Text] The quantitative and qualitative increase in coal extracted and, on this base, electric energy obtained from cheap sources available in the country--a goal of maximum importance for the entire economy--makes it necessary to increase the efforts of all factors involved: the mining units, the enterprises which supply technological extraction installations, transport and processing, the thermal electric power centrals which produce energy, the geological prospecting units, research institutes and institutes for technological engineering and design and so forth--in order to improve their own activity as well as improve cooperation among themselves. With the wish of identifying new solutions and directions of action intended to contribute to increasing the quantity of coal delivered to the beneficiaries, in this issue we are continuing the REVISTA ECONOMICA analysis of the activity

carried out in the Oltenia coal basin, comparing the opinions of mining specialists and those from the units which supply coal exploitation equipment, on the particularly important problem of the supply with highly productive technological installations and their operation and maintenance.

The Miners' Opinion:Adaptation to the Specific Nature of the Activity and Placing the Technological Equipment Into Operation On Schedule

Coal extraction in the daylight pit at the level of plan tasks means primarily that it is necessary for technological excavating and transport aggregates to exist in the mining units at the level of the supply plan provisions. From this viewpoint, the difference existing between forecasts and achievements should be signaled in the delivery, assembly and the start into operation of the excavators and the dumpers. Of the 7 and 3, respectively, that were to be honored by suppliers in 1979, until now only sets of incomplete subassemblies have been delivered from the first two excavators.

The situation is being prolonged this year, too, when the mining units up to now have not received any from the task of the supplier units to deliver a number of other large-capacity excavators. Given the fact that in 1980 some seven technological lines with a total capacity of 14 million cubic meters excavated should be put into operation in the second half of the year, in conformity with the forecasts, it is necessary for the supplier units to concentrate their efforts on a priority basis on building all the equipment contracted and sending it urgently to the mining operations in Oltenia, equipment whose schedules have currently expired.

Another aspect with negative consequences for the activity of placing the new coal extraction capacities into operation is the poor organization of activity for assembling the equipment in the pits, which, instead of being carried out in 4-6 months lasts even more than 12 months. Why? A first reason is that the suppliers deliver subassemblies which they build in tens and hundreds of small parts, despite the fact that they assemble them beforehand when they are subjected to technical testing. It is, among other things, a matter of metal products for excavators, the supplier being the Satu Mare Unio Enterprise, and conveyor belts , the supplier being the Filipestii de Padure Mining Equipment Enterprise. At the same time, it also should be remembered that many times the component parts arrive at the beneficiary in an order other than the one needed in accordance with the assembly technology.

A possible solution would be for the supplier unit to assemble the equipment--of course, with the help of the beneficiary where necessary--and turn it over to it depending on the point at which the parameters forecast are reached. However, until then, the current method of understanding of the obligations belonging to some suppliers--true, it is easy for the producers--should immediately be replaced with a more responsible attitude which takes into account the interests of the national economy in conformity with which the installations must arrive at the job site already assembly by the enterprise which built

them, verified technically and operationally very well. In this way a high net quality and productivity for the assembly would be achieved and there would be a substantial reduction in the length of time it takes to place the new aggregates into operation.

Rapidly reaching the parameters forecast and maintaining some high indicators of utilization for the existing aggregates in operation, as we know, bring the quantity of coal extracted directly. As a result, the lags recorded in 1979 and in the period which has passed this year for some main groups of technological equipment--between the planned indicators and those actually achieved--must be analyzed more carefully; it is a matter of excavators (plan--85 percent, fulfilled--62 percent), bulldozers (85 and 62 percent, respectively), tip trucks (75 and 50 percent, respectively), driving subassemblies (85 and 81 percent, respectively) and stoping combines (86.5 and 85 percent, respectively) and so forth. What have been the main reasons?

Specialists from the Rovinari Mining Enterprise have pointed out that for some equipment (bulldozers, dumpers, hydraulic installation from the floor of the support complex for the driving combines, action station for the belt transporters for underground--supplier, Ploiesti CIUTPM) some differences have appeared between the performances provided in the draft and those required by the specific conditions for operation in the mines and pits. For existing bulldozers, for example, the motors' capacity is lower than the one required by the technology for pit operation. Also, it is felt that the current types of tip trucks delivered are not in agreement with the specific nature of the difficult working conditions imposed by doing the stripping jobs in the pits, which brings frequent interruptions in operation, reduction in the quantity of coal extracted and transported to the beneficiary compared with the plan forecasts. Under these conditions, with the help of 600 auto mechanics and a 60-million-lei consumption of spare parts, in 1979 an active stock of only half the number of tip trucks existing in the supply was maintained and a production of around 1,250 tons/ton of transport capacity (compared with the 3,000 tons per ton of transport capacity planned).

It is felt for the specific requirements of daily operations in the Oltenia basin that what are needed are types of tip trucks with transmission and hydraulic systems which are larger and stronger than the ones supplied until now.

At the same time, it was felt that the finalization of improved technologies and equipment which would permit a selective extraction of coal and reduction in the volume of debris transported and better utilization of the thin veins of useful substances are needed. To carry out these requirements, specialists from the mining combine feel it is especially necessary for the researchers and designers from the Ministry of the Machine Building Industry to make a more thorough study on the spot of the specific working conditions in the pit and work out and deliver extraction and transport equipment for the coal which is better adapted to the specific nature of work in the day operations, with higher productivity and durability.

In other cases, the indicators of utilization of some machinery--and clearly the quantity of coal delivered--have been considerably smaller due to the inappropriate "service" given by the supplier units (such as, for example, the Braila Progresul Enterprise and so forth) on the maintainence and repair of 130 bucket excavators and more than 400 bulldozers. And this is because a number of assimilations of subassemblies which are conditions for the good operation of the existing equipment are behind at the producers; for the suppliers from the machine building industry, it is a question of (centrals) of Lindon pressure, segments and cylinders of motors for the Promex excavators; for the suppliers from chemistry, the adhesive for sticking the rubberized conveyor belts.

The Opinion of the Suppliers of Technological Installations: Improvement in the Use and Maintenance of Equipment

In the investigation carried out among specialists from the suppplier units to find solutions which would lead to speeding up the process for assimilation of appropriate installations for the specific conditions for the exploitation of coal in the Oltenia basin and to raise the level of endurance of the equipment delivered, we discovered some particularly interesting viewpoints. In agreement they feel that the beneficiaries have a contribution which is not at all negligible in the appearance of some shortcomings which reduce the indicators of use of the equipment for exploitation. The machine builders maintain that if some discrepancies appear between the characteristics of the equipment and the specific mining exploitation conditions, this is due to the provisions of the technical-economic operations documents worked out by the Institute for Mining Research and Design,which even is the beneficiary's and which, probably, did not take all the necessary factors into the initial calculations. The examples offered refer to certain digging equipment which deteriorated, since it was made to work under conditions which were 1-4 times more difficult than what was provided in the draft or support poles which were not adequate for the actual tasks, which were much greater ,and this actually led to the equipment's being buried and stopped. Given the fact that the production units respect the provisions in the draft, it is necessary that the work drafts by the beneficiary not contain merely the ideal working conditions at the command of the technological equipment but that account also be taken of the real and complex difficulties involved in the pit operation and the probability of the eventual appearance of some more difficult operating conditions.

With regard to the assimilation of new, improved equipment needed for the exploitation of coal, it should be pointed out that if it is true that some lags in this area are due to the producer, it is just as true that the beneficiaries in turn create some shortcomings. First, it is a question of the fact that they change their options much too often (many times it is even during the plan year) on the quantity and quality of technological equipment requested (particularly, digging aggregates and support poles). Of course, the production plan for the producer is not rigidly fixed, yet, given the long length of time needed objectively for appropriate preparation of the manufacture, it is necessary for the beneficiary to better substantiate the supply need on time through a more adequate utilization of methods of technical and technological prognoses.

Second, it is necessary for the mining units to collaborate more actively with the production enterprises in a more efficient homologuing of the newly assimilated aggregates, because currently there still are cases (for a new digging combine aggregate produced on the basis of Romanian design by the Satu Mare Unio Enterprise, for example) when the technological equipment of Romanian design although being utilized with good results in the exploitation by the beneficiary, which have not been homologated by them in order not to reduce the possibility of having to appeal to a future import.

Not only the producers should be blamed for the inappropriate maintenance of certain equipment, but also the IUTCCR Enterprise should be mentioned; it has in its supply the auxiliary equipment (bulldozers, bucket excavators, graders and so forth). This unit does not always succeed in providing that the operations for the maintenance and repair of the equipment is carried out quantitatively and qualitatively at the level of requirements. The main reasons are lack of spare parts, of personnel, of the capacity for maintenance and repairs, lack of strict respect for technological and for labor discipline, that is, reasons which can be corrected fast. At the same time, it should not be neglected that beneficiary mining units (primarily Rovinari, Jilt and Rosia mining enterprises) of these extraction and transport equipment do not provide conditions for normal operation everywhere: Many roads are improvised or not built and maintained properly, in other cases they are missing altogether and sufficient technical assistance is not being given in carrying out work in the pits and so forth.

A possible solution which deserves to be taken in the specialists' analysis in order to eliminate these shortcomings could be for the auxiliary extraction and transport equipment to move into the supply of the mining units, which would bring more concern with their appropriate exploitation and maintenance, reduction in technical, scientific and administrative personnal and auxiliary personnel by around 30 percent, a halt to the "passing" of responsibilities between the holder and the user of the machinery and so forth. But until then, the question which naturally arises from the analysis of the shortcomings presented is why the efforts of the units which hold and utilize the machinery--and which actually all belong to the Oltenia Mining Combine--are not better correlated. Why does not the combine coordinate the collaboration of these enterprises even more exactingly with a view to the better operation and maintenance of the extraction and transport equipment? In this regard it would be useful for the investments directorate in the combine not to consider closed its mission together with putting into operation or starting into operation the new capacities for exploitation and transport and to provide technical assistance and all the necessary aid with more consistency until the parameters forecast are reached for all the technological equipment as, for example, happens occur at the thermal electric power centrals.

On the other hand, it should be noted that certain teams for the "service" and repair of the supplier have found other lacks at the beneficiaries, too, in the operation and, in particular, the maintenance of technological equipment.

For example, it is a question of the technological conveyor belts for the coal extracted, whose rubberized covers often tear and due to the fact that the beneficiary does not provide clean rolls or keep the heads of the belts clean from a coating of coal which through continual friction wears the conveyor belt out. Really, recently concerns in this direction have increased in the sense that the Rovinari Mining Enterprise through its own supply built installations for cleaning the coal under the belt and the rolls, but they still are not operating continually and there are not enough for the existing number of conveyor belts. For that reason, for the large-saale production and quality production of these installations, broader efforts must be made by the mining units, but also by the machine building units, intended to lead to the generalization of the good experience accumulated until now.

Many shortcomings, at the same time, also create the fact that sometimes in the mining enterprises the technological installations are not appropriately stored, which means that they deteriorate, many times irreparably. An example is graphic: A number of subassemblies needed for the driving combines were stored in this way, so that, actually, access was blocked to the first samples brought into the warehouse, which meant that only the newly delivered ones could be utilized. As a result, since 1976 many of these kinds of subassemblies have remained stored and blocked and their rubber gaskets--indispensable to their good operation--have deteriorated completely, making the entire part inappropriate for use.

In the end, it is felt that a much greater effort is needed in all mining operations to raise the qualification of the personnel, which would lead directly to recovering some lags in operation at the high indicators of the machinery, to longer life for the equipment and, implicitly, to increasing the volume of coal extracted.

So there is a diversity of opinions which, in our opinion, can be taken into consideration by the factors concerned. First it is necessary to create a spirit of favorable collaboration so that the participation of the suppliers of equipment as well as of their beneficiaries in solving the various problems which appear inherently can be efficient and effective. It is in the interest of everyone that high-performance equipment be built, that the most favorable conditions be created so that they can be used at their full capacity, so that the programs for greater growth in coal production can be achieved totally. In this way the thermal electric power centrals, in turn, having the needed coal, will be able to fully utilize the capacity of the installations in their supply, producing and supplying to the national economy electric energy at the level demanded.

REPUBLIC FOREIGN TRADE IN FIRST 6 MONTHS

Belgrade PRIVREDNI PREGLED in Serbo-Croatian 8 Aug 80 p 6

[Article by Milorad Urosevic]

[Text] According to the unified projection of the country's balance of payments and foreign exchange balance for this year, by the end of the year the greatest efforts to achieve the planned balance of payments effects should come in Slovenia, Serbia and Vojvodina.

The Resolution on the Unified Balance of Payments of the Country for 1980, which was approved by the Council of Republics and Provinces of the Yugoslav Assembly at the end of July, signified the end of the temporary resolution based on the law passed at the end of last year when agreement could not be reached on the level of the deficit of payments as a part of the resolution for this year.

Even at that time, the Federal Executive Council insisted that the deficit of payments this year should not exceed $2 billion. In the intervening time, there was a change in the dinar exchange rate that will have various effects on exports and imports, depending primarily on the competetive capabilities of various branches of the economy on world markets, and of individual organizations of associated labor, where exports are involved, and of increasingly scarce foreign exchange, where imports are in question.

Trading abroad in the present circumstances and with the likelihood that new unfavorable trends are coming in international markets will not be easy, and therefore the Resolution on a Unified Balance of Payments Policy is an important support. Now each republic and province will know what kind and how much economic activity it is to provide, in order for this national "be confident in yourself" process to prevail.

Points of Departure

Since the Law on the Temporary Projection was in effect fully 7 months, and since immediately before the approval of the resolution in the Yugoslav Assembly the Federal Statistical Office published data on foreign trade in the first 6 months of the year, the points of departure for the republics and provinces can be prepared.

Taking into consideration the planned percentage of increase in exports and increases or cuts in imports, the picture is as follows:

(1) Republika-pokrajina	(2) Ostvareno 1979. u mil. dinara		(5) Projekcija za 1980. godinu			
			(6) Baza 1979, + - %		(9) Plan u mil. din.	
	(3) Izvoz	(4) Uvoz	(7) Izvoz	(8) Uvoz	(10) Izvoz	(11) Uvoz
(12) Bosna i Hercegovina	15.527	27.007	29,2	17,3	20.061	31.679
(13) Crna Gora	1.921	4.987	21,3	34,4	2.330	6.703
(14) Hrvatska	29.720	64.423	32,0	- 6,0	39.230	60.558
(15) Makedonija	6.150	14.248	34,4	- 6,1	8.226	13.379
(16) Slovenija	22.524	37.891	34,7	- 10,0	30.340	34.102
(17) Srbija	28.856	46.046	38,9	- 3,2	40.080	44.573
(18) Kosovo	2.738	5.769	31,6	23,3	3.603	7.113
(19) Vojvodina	8.510	20.394	45,4	18,2	12.374	24.106
(20) SFRJ	103.437	182.286	34,9	0,2	139.537	182.652

Key:

1. republic or province
2. 1979 total in million dinars
3. exports
4. imports
5. projection for 1980
6. 1979 base, + or - percentage
7. exports
8. imports
9. plan in million dinars
10. exports
11. imports
12. Bosnia and Hercegovina
13. Montenegro
14. Croatia
15. Macedonia
16. Slovenia
17. Serbia
18. Kosovo
19. Vojvodina
20. All of Yugoslavia

The table shows that the relation between exports and imports in all socio-political communities, and in the federation, must be much improved at the end of this year over last year, with the percentage of exports covered by imports for the whole country increasing from 0.5 [sic] percent last year to 76.4 percent at the end of the present year. Regarded by republics and provinces, the amount imports are covered by exports is expected to vary from about 35 percent in Montenegro (for which there are justifiable causes) to 51 percent in Bosnia and Hercegovina, 61 percent in Macedonia, 65 percent in Croatia, to 90 percent in Slovenia and Serbia proper. The reasons for these great differences are certainly numerous and not the most objective, and these factors were described in the communique on the approval of the resolution, but they should be seen as a contribution to the agreement process. It should be noted to what degree individual republics and provinces have already achieved their targets as presented in the resolution.

Differences in Achievement

Even if something markedly more unfavorable does not occur in international markets in the remaining 5 months, the first 6 months were certainly less favorable for exporters due to the unrealistically low exchange rate for

the dinar, which supported imports. That had the effect that the growth of exports, while amounting to something more than half of the planned rate, lagged markedly benind the growth in imports above the planned level. It can, however, be hoped that in the second 6 months the deficit will be held within the planned limits because of the more realistic exchange rate for the dinar and other circumstances.

The remaining targets of exports and imports to be reached by particular sociopolitical community in the second 6 months are shown in the following data:

(1) Republika-pokrajina	(2) Ostvareno za 6 meseci				(3) Ostaje da se ostvari			
	(4) mil. dinara		(5) % od plana		(6) Izvoz		(7) Uvoz	
	(8) Izvoz	(9) Uvoz	(10) Izvoz	(11) Uvoz	(12) Mil.	%	Mil.	%
(13) Bosna i Hercegovina	11.261	17.976	56,1	56,7	8.800	43,9	13.703	43,2
(14) Crna Gor	1.025	2.539	44,0	37,9	1.305	56,0	4.164	62,1
(15) Hrvatska	19.196	36.064	48,9	59,6	20.034	51,1	24.494	40,4
(16) Makedonija	3.400	6.758	41,3	50,5	4.826	58,7	6.621	49,5
(17) Slovenija	16.505	24.823	54,4	72,8	13.835	45,6	5.279	27,2
(18) Srbija	18.604	27.045	46,4	60,7	21.476	53,6	13.035	39,3
(19) Kosovo	1.774	3.509	49,2	49,3	1.829	50,8	3.604	50,7
(20) Vojvodina	5.929	15.486	47,9	64,2	6.445	52,1	8.620	35,8

Key:

1. republic or province
2. 6-month results
3. remaining quota
4. million dinars
5. percent of plan
6. exports
7. imports
8. exports
9. imports
10. exports
11. imports
12. millions
13. Bosnia and Hercegovina
14. Montenegro
15. Croatia
16. Macedonia
17. Slovenia
18. Serbia
19. Kosovo
20. Vojvodina

Compared to the approved unified balance, Bosnia and Hercegovina and Kosovo have very equal rates of exports and imports, with about 56 percent and 49 percent respectively, so that in the second 6 months they will only have to continue to fulfill their export and import quotas as they have in the first 6 months. Montenegro is the only sociopolitical community that has, in relation to its position, fulfilled a larger part of its export target than of its projected imports; all other communities have the opposite record.

Croatia has fulfilled 48.9 percent of its export target, but has imported just under three-fifths of its annual quota, indicating that in the second 6 months it will have to practice considerable forebearance, as will Macedonia where 41.3 percent of the export quota, and 50.5 percent of the import quota, have been fulfilled. Slovenia has exceeded its export target for the first 6 months by 4.4 percent, but on the other hand, it has used 72.8 percent of its annual import quota. Serbia has exported 46.4 percent of its yearly

quota, and imported 60.7 percent of its annual allotment. After Slovenia the situation in Vojvodina is the least favorable: in 6 months it has fulfilled 47.9 percent of its export target and 64.2 percent of its imports.

Judging from all these data, in the remaining 5 months foreign trade will require maximum efforts to fulfill the agreement and hold deficits within the planned limits.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

INDUSTRIAL ACTIVITY DURING JANUARY-JULY 1980

Sofia IKONOMICHESKI ZHIVOT in Bulgarian 13 Aug 80 p 4

[Article: "Industry of People's Republic of Bulgaria during January-July, 1980"]

[Text] The plan on monetary return from industrial production for the 7-month period of the year was 99.7 percent fulfilled. It was fulfilled as follows at some of the ministries:

Ministry of Energy--102.2 percent, Ministry of Machine Building--102.1 percent, Ministry of Light Industry--102.1 percent, Ministry of Metallurgy and Mineral Resources--101.1 percent, Ministry of Electronics and Electrical Engineering--100.9 percent, Ministry of Chemical Industry--101.0 percent, Ministry of Internal Trade and Public Services--100.5 percent.

In July the rate of production growth increased 6.2 percent, whereas in the 7-month period 4.6 percent more industrial production was realized over the same period of the past year.

The production of some basic commodities was:

Products	Measure	Output in Jul	Output in Jan-Jul	Jan-Jul 1980 in percent as to Jan-Jul 1979
Electric Power	Mil. kW/h	2,484	20,004	106.5

Committee on Unified System
of Social Information

Commentary

Production grew in July at a higher rate than during the first 6 months of the year. It should be pointed out, however, that the production in July

was smaller than in June. The July plan for commodity production was fulfilled 99.8 percent with 358 industrial branches not fulfilling this indicator.

The Ministry of Construction and Construction Materials, the Ministry of Forests and Forest Industry, the National Agro-Industrial Union and other organizations have been lagging behind in the production plan for the January-July period. This affected their total revenue and their allocation of means needed for their funds for the economic organizations and their branches.

There was a drop in the production of some important products as sheet iron, phosphate fertilizers, automobile tires, lathes, motor trucks, cement and others.

According to the analysis of the reasons for nonfulfillment of the plan, the drop in production was caused mainly by not fully utilizing the production capacities as well as the labor force due to:

--poor technical conditions of some of the machines and equipment and frequent stoppage of the production process caused by unexpected repairs;

--irregular supply of raw and other materials and noncompliance with the contractual obligations concerning cooperative supplies;

--poor labor organization, and violation of the labor and technological discipline.

These shortcomings are most typical for the beginning of the month when in many enterprises work time is lightheartedly wasted without adhering to the production program. During the first 10 days of July, for example, the commodity production plan was fulfilled 95.3 percent whereas during the 20 days period, only 92.8 percent. In many of the economic organizations and departments almost half of the monthly output is produced during the last 10 days; in July it reached 46 percent. Therefore, a better production rhythm continues to be the main factor for guaranteeing the fulfillment of the production plan and reaching the goals of industry. The production rhythm should be observed each workshift, each single day, week, and month.

Furthermore, production agreements should be made to involve a shorter period of time as concerns the supplies for production which on its part will speed up fulfillment of the plan for transferring the monetary returns to industry.

SURVEY OF VARIETIES FOR HIGHER WHEAT YIELDS

Sofia ZEMEDELSKO ZNAME in Bulgarian 29 Aug 80 p 2

[Article by Senior Scientific Associate Todor Rachinski, director of the Wheat and Sunflower Institute in General Toshevo: "Optimum Wheat Strain Structure!"]

[Text] This year wheat production in Bulgaria marked a new considerable success. For the first time the average yield for the country exceeded 400 kilograms of grain per decare. Once again the leading okrugs obtained over 500 kilograms per decare while the best brigades, and masters in the production of grain crops reached yields in excess of 600 kilograms per decare. A general upsurge and a marked aspiration to go forward and upward in wheat production is visible. What is most important is that the results which were achieved have triggered new ambitions and searches in the area of mastering the fine points and details of the production process.

Unquestionably, these successes are the result of the application of modern highly intensive growing technology, consistent with natural and agroecological conditions. They are the result of the extensive application of scientific knowledge, of a specific approach, greater experience, and higher technological discipline and, not least, the exceptional care with which our people are growing this crop.

We must also properly acknowledge the importance of strains.

The Most Important Biological Fertility Factor

The effect of all agrotechnical measures and natural influence factors is refracted through the quality of the strains. The more intensive wheat production becomes, and the higher our objectives are set in terms of high yields, the more the production process becomes dependent on heredity characteristics and strain genotypes. It is universally acknowledged that the greatest reserves for increasing yields may be found in the biological improvement and increased variety of the strains. This is particularly important to our country in which the specific nature of natural conditions limits the effect of increasing the dosage of the basic intensive factor--fertilizers.

A great advantage of our wheat production is also based on the fact that it is being developed with a richer strain structure. Today the ability to use the positive qualities of the strains means not only knowledge of how to raise the individual strain but also how to combine strains under specific soil, topographic, terrain, and production conditions. Each agroindustrial complex, brigade, or production sector has microrayons with specific conditions considered suitable or less suitable in terms of individual strains.

That is why one of the important requirements of modern scientific and technical progress in wheat growing is the accurate and practically confirmed microzoning of the strains.

Claims that we should "squeeze out" to a maximum the possibilities of a given strain before looking for another one are not only unscientific but represent a hindrance to the utilization of the advantages of the most successful strain combination. These claims are dominated by the theory of the "ideal" strain, which could hardly ever be developed. They turn us back to the use of a single strain despite all its disadvantages. They try to extend the monopoly use of a single strain even though other equally good or even better strains exist. Should we adopt such a strange structure for wheat we would be deprived of a considerable and still insufficiently used possibility for further yield increases.

We have an adequate and adequately tried selection of wheat strains whose genetic potential meets modern production requirements. We are raising about 20 strains. However, two are of leading significance: Sadovo 1, which is basic for southern Bulgarian, and Dobrudzha 1, for northern Bulgaria. In northern Bulgaria Dobrudzha 1 offers a substantial advantage because of its better resistance to diseases and its ecological plasticity. Currently this strain is displaying the best possible qualities for a mass type of wheat, with great stability and reliability of yields, equally displayed in both bad and good years. Under the conditions of southern Bulgaria, where wheat diseases are lesser, Sadovo 1 is displaying very great resistance to drought and yield reliability. Naturally, the peak of the Balkan Mountains should not be considered the boundary dividing the areas where the two strains are raised. Results have indicated that Dobrudzha 1 has high yields also in Burgas, Sliven, Pazardzhik and Sofia okrugs, while Sadovo 1 gives high yields in Varna and Shumen okrugs.

The Slavyanka strain is acquiring ever greater production significance. This is a high grade strong wheat with very good productive possibilities. Areas planted in this strain will be concentrated mainly in southern and northwestern Bulgaria. The tendency is to convert it into one of the basic strains used in these areas. The production of high quality grain, for the time being, will involve mainly the use of the Slavyanka strain. The most suitable areas for its use must be defined and suitable agrotechnical and technological methods must be applied to boost the quality

of the grain and insure the growing of the necessary quantities of strong wheat grain for the country.

Production intensification calls for broadening the area's short-stalk strains whose productive possibilities are higher. The Vratsa, Yubiley, Trakiya and Ogosta strains have already passed their extensive industrial tests and proved their high productivity. Yields in excess of 650-700 kilograms per decare from such strains were obtained over large areas. Currently, such wheats account for about 15 percent of the area in wheat. It would be expedient, however, to expand this area in the next few years to 30-35 percent. The Vratsa strain has shown extensive ecological adaptability and the possibility to be used in all parts of the country. It is particularly promising in the intensive wheat areas of sourthern Bulgaria. Yubiley has proved to be a strain yielding stable high crops with noted advantages compared with remaining strains in the case of moist and more disease-ridden wheat seasons. Trakiya is proving to be the proper strain for dryer and warmer areas with rich soils. The great possibilities of the Ogosta strain are being confirmed in the area of carbonate chernozems, along the Danube and in the plains of northeastern and southeastern Bulgaria.

The intensive short stalk strains do not have the great ecological plasticity of the Dobrudzha 1. However, it is mainly they that yield over 650-700 kilograms per decare, providing that strain agrotechnology requirements are strictly observed.

Even though showing greater yield fluctuations, the early ripening Vega and Zlatoklas strains offer us good possibilities to advance the harvest season. Vega is more suitable for the plains with higher soil fertility, while Zlatoklas is better for slanted and eroded fields with less fertile soils.

The Kaliakra 2 strain has yielded very good results in the higher and cooler plateaus. Under similar conditions and with poorer soils, the use of the Kiten strain offers very great possibilities.

Phytosanitary considerations are prevailing to an ever greater extent in the selection of strains and in optimizing the wheat strain structure. This year's results as well have indicated that strains sensitive to the brown rust have had the lowest yields. Such yields were reduced by over 100-150 kilograms of grain per decare. The Yubiley, Ogosta, Trakiya, Kiten, Charodeyka and Zlatna Dolina strains have shown high and stable resistance to this disease, while Dobrudzha 1 and Vratsa have shown very good such resistance. The Sadovo 1, Trakiya, Yubiley, and Ogosta have proved to be very resistant to the yellow rust, while the new Kubrat 1, Tervel and Terter strains have shown very good resistance to the black rust.

The Yubiley, Vratsa, Trakiya and Charodeyka strains are the most resistant to flattening and suitable to high altitudes. Bezostaya 1, Sadovo 1, Slavyanka, Yubiley, Trakiya and Vega are the most resistant to frosts. Slavyanka, Ludogorka, Ogosta and Vratsa are highly resistant to grain casting.

Thanks to intensive and purposeful selection-improvement work with wheat, our strain structure is becoming steadily richer and better. A new increase has been achieved in the production potential of the strains. The Charodeyka strain, with a potential of over 800 kilograms of grain per decare, is already being rapidly used.

Determining the best strain structure of wheat is an important and exceptionally responsible problem. Its solution cannot be accomplished by passing decrees, or through indifference or subjective ideas. The best strain structure will be achieved by those who are steadily searching and experimenting with new developments, who acquire personal experience and impressions, who study strains under specific conditions, and who are best informed of their qualities. Let us sow the best strains and let us develop for each strain the best possible conditions so that it could yield its highest output. It is with such increased exactingness that we must enter the Eighth Five-Year Plan in order to conquer new peaks in the production of more wheat grain.

INDUSTRIES ADAPTING 'MEASURES' TO LOCAL CONDITIONS

Prague HOSPODARSKE NOVINY in Czech 8 Aug 80 p 3

[Article by Eng Vaclav Filip, employee of the Secretariat of the Governmental Committee for Problems of Planned Management of the National Economy: "Set of Measures: Its Applications in Industrial Branches--Upgrading the Planned Management System"]

[Text] Specification, discussion and endorsement of the application of basic indicators of the plan and other tools of management according to the conditions in individual branches of our industry have represented an important stage in works connected with planning and implementation of the Set of Measures for Improving the Planned Management System of the National Economy after 1980. One of the basic principles in the planned management system has been applied: namely, a diversified approach to individual branches and sectors of industry.

Applications to conditions in individual branches are necessary because the Set of Measures was planned mainly for industry and does not reflect the specific characteristics of the nonindustrial branches, as well as of certain industrial branches, particularly basic production (the type of technology, natural conditions, concentration of production and management, seasonal character of operations, biological conditions, foreign relations, etc.). At present central organs are preparing specifications for the Set of Measures to be applied in the management system of their ministries.

In the first place, contradictory and divergent demands had to be eliminated from proposals presented for specific solutions, and solutions with equal validity for various branches had to be selected from such proposals.

General Standards

Organizations of the same type (industrial, construction, scientific research centers, marketing, etc.) will follow identical regulations irrespective of the ministry of VHJ [economic production unit] in which they are organizationally incorporated.

The sales value indicator for consumption in production will be applied step by step, and serve at first for orientation, in agreement with the State Planning Commission. It has become evident that the plan thus far has not created preconditions for the determination of this indicator; if introduced, this indicator could even negate to some extent the interest in reducing material consumption in production. Thus, in the next stage of the solution of this problem, attention must be focused on mandatory material indicators in order to guarantee supplies for consumption in production.

Tasks related to deliveries for capital investment, broken down according to selected sectors, will be determined gradually, according to agreements between branch ministries and the State Planning Commission, which will gradually create the preconditions and foundations for the plan.

Mandatory technical economic parameters will be stipulated in all ministries on individual management levels as a part of assigning each task of the technical development and its implementation, tasks in planning, etc.

A ceiling of 2 percent of wages payable is valid for allocations to the fund for cultural and social needs, with the provision that another quota of up to 0.4 percent may be allocated from preferential pricing of technically advanced goods, first-quality products, and fashion and luxury goods. If the type of production or of the activity of the VHJ excludes preferential pricing, another indicator characteristic for conspicuously improved quality of work or efficiency may be adopted by agreement. Another contribution of 0.4 percent (i.e., up to 2.8 percent) may be allocated only pursuant to the regulations applicable for export incentives. The opportunity to achieve the 2.8 percent ceiling is open exclusively to the exporting VHJ and stipulated intentionally so as to give priority to foreign trade.

The fund for development will be established in nonindustrial organizations, if the organization in question participates to a significant degree in industrial, construction or repair programs (this principle does not apply to organizations managed by national committees, because as a rule, the fund for development will not be organized in that economy in view of the general planning and financial attitudes toward the national committees as a whole).

Peculiarities of the Industry

As for the adaptation of the Set of Measures to the conditions in individual ministries, I present here only the most important applications in individual central organs and in the economy managed by national committees.

In the branch of fuels and power engineering, the applications respect the idiosyncrases of natural conditions, the limited resources of raw materials, the deteriorating mining conditions, the impossibility of storing electric power, and also a high share of the labor value added. In the production and sales areas, unlike in other indistrial branches, the plan will not

stipulate the task of the share of technologically highly advanced products. The growth of per kg prices will be stipulated to a limited extent. The ceiling for the number of workers may be exceeded in cases of hiring persons with altered work capacities.

The main component of wage funds will be set absolutely by the VHJ and, unlike in general solution, it will not be reduced in case of nonfulfillment of production goals. The incentive component of wage funds in the production of fuels will not depend on the profitability of the means of production, but created according to transferred natural units. In power and gas generation the correlation with the profitability of the means of production is replaced by the indicator designating efficiency and quality (for instance, specific fuel consumption per kilowatt). The conditions for the achievement of the above-plan incentive wage component are then selected so that the interest in the material volume of production will be complemented by efficiency--which, in case of fuels, means a selected indicator (for example, costs required), and in power engineering, for instance, available capacity.

Diverse natural conditions call for redistribution of profits by the ministry. The development fund will be established in organizations where such opportunities exist in terms of production of their own financial resources, i.e., primarily in machine engineering and assembly enterprises. Centralization of credit relations in the VHJ for subordinate enterprises will depend on the extent of centralization in capital investment, supply, and other areas of management, which will be stipulated in statutes and regulations valid within that particular VHJ.

In organizations of the Federal Ministry of Metallurgy and Heavy Engineering, General Engineering and Electric Industry, the deviations from the Set of Measures are minor. Partial specifics are respected in machine engineering organizations with higher supplier functions and in marketing and supply organizations where a risk fund may be established to cover certain multiple costs.

In ferrous metallurgy the incentive wage component will be created differently; it will be determined by cost requirements instead of profitability of means of production, and furthermore, the qualifying indicator of sales structure will be replaced by structure of production in material units (coke and pig iron). In engineering metallurgy it is exceptionally permitted to stipulate the limit for external rejects in order to determine the extent of inferior products. In the Ore Mines and Magnesite Works VHJ, certain deviations will be in effect (for example, profits instead of profitability of means of production, the basic component of wages payable absolutely unrelated to outputs, analogically as in fuels). In planning and implementation, the Set of Measures will be further adjusted so as to control price limits and to stipulate the increase of per kg prices and the opportunity to exceed the limits imposed on the number of workers by hiring persons whose ability to work has changed.

In organizations of the chemical and consumption industries no specific deviations have been approved.

Adjustment in Other Branches

In construction industry the Set of Measures will be applied analogically as in industry, with adjustments reflecting the type of operations in the construction industry, which differ from industrial production. This leads to frequent changes in the organization of work, and to a more pronounced role for transportation in the construction industry. Also, profitability of production thus far and the financial base of the organizations themselves are taken into consideration. Profitability of operating assets (after modification by clearing the unfinished construction production), profitability of factors of production (to be tested in selected VHJ of construction materials), and profitability of costs will be applied as summary indicators expressing the overall activity of the organizations. In addition, the questions concerning the establishment of the development fund and concerning the so-called "debt removal" of construction organizations on the basis of submitted quantifications are still under discussion.

In forest and water economy its specific character will be applied in several directions. In view of the scope and character of capital investment, the development fund will not be established here. The output in these branches is expressed by the so-called planning prices (in forest economy, value added; in water economy, outputs) which will comprehensively affect the operation of those organizations. Furthermore, outputs in planning prices will then serve as the base for the control of the basic wage factor.

In forest economy profitability of the operating factors will be applied in lieu of profitability of operating assets; in correlation with this adjustment, the incentive wage component is then linked with the adjusted indicator of factors of production (instead of profits, the volume of value added will be applied in planning prices). In water economy the basic wage component will be controlled by total outputs with regard to the lowest possible material consumption.

In transportation and communications the distinct character of operations--satisfaction of the needs in other branches--is respected; reduced capacities here (in transportation) may mean a social contribution, so long as the demands of the transport workers are met. Moreover, the fact is taken into consideration that the production of the utility value of goods is completed in freight transport. However, no material utility value is created there.

In output plans the indicators expressing specific aspects of transportation and communications services are applied, and the indicator of profitability of operating assets has been replaced by profitability of costs.

In state agricultural organizations specific natural conditions and the effect of biological laws on production are taken into consideration. The indicator of total outputs is retained in view of the time factor of investments in the land and of the seasonal character of agricultural operations. At the same time, however, the switch to the units of manpower consumption or some other appropriate indicator (for evaluation as well as for wage control) will be experimentally tested in 1981-1982.

Profits which will constitute the basic indicator of the financial plan will serve as a basis for the creation of the incentive wage component. By the same token, the principle was adopted that the results achieved by agricultural organizations will be adjusted on a nonaccount basis by the effect of abnormal weather conditions. The development fund will not be established here; profits may be redistributed within the ministry.

In the food industry the indicator of value added and profitability of operating assets (or factors of production in seasonal production) will be applied. Naturally, they will be modified so that, for the purposes of evaluation of plan fulfillment and for wage control, the indicators will be adjusted by the effect of nondeliveries of agricultural raw materials and of control measures on the part of governmental authorities. When converting the amount of supplies for the purposes of profitability of operating assets and of their turnover rate, the seasonal character of the branches of food industry will be taken into consideration, and supplies of a seasonal type will be excluded. Specific objective tasks of the plan will replace the qualifying indicator of the marketing structure for above-plan wage resources.

Rather than the value added, the basic component of wages payable in railroads will depend on operational outputs assessed by constant labor costs, and in civilian air transportation and in water transportation by the share of receipts. The incentive wage component will depend on a suitable qualitative indicator other than profitability of operational assets (for instance, profitability of costs and exploitation of the rolling stock and engines).

The development fund will not be established in either branch; investments will be stipulated as directives in the plan. Profits may be redistributed on the level of the ministries, with regard to the financial situation of the organizations.

In domestic trade, i.e., in the branch serving to circulate the goods, retail turnover remains the basic indicator characterizing the operation of the organizations, although the negative aspects of its effect as a volume indicator are well-known. It has been retained because no other solution is available. The task of studying potential alternatives for evaluation of the fulfillment of the plan and wage control, other than retail turnover (for instance, the trade span), before the end of this year has been assigned to appropriate organs.

Profits and the share of total costs will be applied instead of profitability of operational assets, the development fund will not be created, and all investments will be financed from the construction fund.

In foreign trade organizations the monopoly of foreign trade is respected and furthermore, a system of tools that has been introduced will affect the volume of exports and imports and their structure, as well as their efficiency. For that purpose, planning of exports has been intensified in entries in the state plan, and specific investment units will constitute its part. Profits and the share of total costs in outputs (without direct foreign trade costs) will be applied in lieu of the mandatory indicator of profitability of operating assets.

Basic wages payable will not be regulated by value added, but determined absolutely, without any reduction, on the basis of actual outputs. The incentive wage component depends on actual exports in prices quoted; the achievement of an above-plan incentive component will depend on the achievement of the differential indicator stipulated in the plan for the socialist countries and for the nonsocialist countries. Redistribution of profits on the level of the ministry is permitted. The development fund will not be established in foreign trade organizations, and the volume of investments will be determined in a detailed breakdown of the plan.

In health services the Set of Measures will be applied according to each individual organization. In organization of production the type of medical production is respected first of all by the stipulation of mandatory deliveries of supplies for health services; furthermore, in the interest of health care, a reserve fund will be used to balance economic shortfalls, if any, stemming from the regulated production. In organizations managing spas and mineral springs, and in services supplying health care organizations, certain tools of management will be adjusted. For instance, the development of the incentive wage factor will be stipulated in relation to the development of profits, etc.

Specifics of National Committees

An economy managed by national committees is specific in its differentiation, the extent of its services to the population, its diversity and its narrower technical-production base. As a rule, general principles of the Set of Measures are applied here with the deviations states below. Indicators of the plan are adjusted according to the appropriate operations in individual branches.

The regulation of the basic factor in wages payable will deviate from the adjusted value added only in case of restaurants and dining services (correlation with retail turnover, however, the criterion for testing another indicator, applies in the same way as in the case of domestic trade), water economy (outputs in planned prices), in the KNIHA [Book] enterprise (indicator of sales of goods), in local industry and communal services (labor and service indicator).

The incentive wage component is determined on the basis of profitability of total costs, except for municipal mass transportation (on the basis of losses), for restaurants and dining services, the KNIHA national enterprise, and the Coal Storage enterprise (economic results), water economy (costs of materials), and the CSAO [Czechoslovak Automobile Repair Shops], local construction, bakeries and confectioneries (usually profitability of operational assets). The development fund will not be introduced in enterprises managed by national committees. The supply turnover rate will be differentiated, and the enterprises will pay the contributions to the state budget.

Unlike the situation in centrally managed branches (with some exceptions, for example, the Transport Enterprises VHJ in Prague), the enterprise is regarded as the basic unit.

Furthermore, some unification will apply in the economic and legal forms of the kraj organizations for the development of technology in local economy and of engineering investment organizations, which will be organized individually as administration of health and cultural organizations.

The application of the Set of Measures has been adopted in other national economic branches as well, for instance, in planning and engineering organizations, in organizations of the scientific research base, and in geological, educational and cultural organizations.

The above-stated application, approved for whole branches by the Governmental Committee for the Problems of Planned Management of the National Economy, do not fully exhaust every opportunity for the adaptation of the Set of Measures. The Set of Measures also allows partial adjustments in individual regulations which may be applied in individual VHJ's so long as their character justifies them. For instance, in economic production units an indicator other than adjusted value added may be introduced, if it can better express the effect of labor value added. Analogically, profitability of operational assets may be replaced by another indicator that expresses better the efficiency of work for the society. The Set of Measures allows for partial adjustments of specific demands also in other areas.

MINISTRY-VHJ FINANCING PROBLEMS EVALUATED

Prague FINANCE A UVER in Czech No 6, 1980 pp 395-403

[Article by eng Vaclav Maly, CSc]

[Text] At the present time increased attention is being paid to finding ways to improve the Czechoslovak economy's management system. By so doing economists are fulfilling the tasks set for them in this area by the 15th Congress of the CPCZ. In addition to efforts aimed at coming up with improved planning procedures, since these are the primary methods used in the management of a socialist economy, a great deal of attention is also being paid to improving and increasing the effectiveness of indirect economic management methods. At the 15th Congress of the CPCZ Comrade Gustav Husak made the following statement: "We are linking the drive to improve the quality of management work with the demand calling for the more effective utilization of financial, price and wage planning levers. In line with the goals of the plan and in conjunction with the fulfillment of substantive tasks the role of these planning levers needs to be expanded."[1]

A number of specific results were already achieved in the past in connection with the drive to solve the problem of finding ways to improve the management system of the Czechoslovak economy. A comprehensive experiment of efficiency and quality management, one of the key programs of the planned management system of the past few years, was devised and put into practice. In accordance with the rules of this experiment the effectiveness of the economic levers of indirect management is being enhanced. In 1977 the impact of economic planning levers in the area of financial management was also bolstered and upgraded through the passage of legislation that introduced modifications into the system of levies and taxes paid by economic organizations into the state budget and the national committees budget, legislation which went into effect on 1 January 1978.[2]

These taxation law amendments are a direct result of the restructuring of wholesale prices on 1 January 1977 and mark the culmination of readjustments of financial management instruments used for the Sixth Five-Year Plan.

These trends, which are clearly visible in the process encompassing the refinement of the management system of our socialist economy, are the focal point of this article; in this article we will be discussing certain aspects of financial management at the branch-ministry level.

Financial Policy as a Management Tool

One of the important tools used by the branch ministry to carry out its economic management functions vis-a-vis subordinate economic organizations (primarily VHJs) is its financial policy which is defined most concretely in the system employed for the formation and utilization of so-called ministry funds and in the system used to redistribute financial resources.

The existence of funds at the branch-ministry level and, most importantly, the system used for the redistribution of financial resources has its progressive aspects, but, at the same time, this arrangement also poses certain theoretical and practical problems.

The financial resources redistribution system is a very effective tool for managing the formation and spending of financial resources at any management level. But at the same time, speaking from a theoretical standpoint, there is something about this arrangement which in a system of management controls points to the existence of imbalanced financial relations, with all of the drawbacks inherent in these relations.

However, the redistribution system is above all a management tool. And as with any tool its effectiveness is primarily a function of the way in which it is used. If redistribution is used to balance out the uneven economic performance records of various organizations without bothering to analyze the causes of these discrepancies, then this tool is in fact being wielded in a manner that contradicts the principles of khozraschet management and, in the final analysis, diminishes the effectiveness of the management system as a whole.

On the other hand, if the redistribution system is used by managers in an active way, i.e., in conformity with the goals of the system as a whole, then this concept goes a long way toward limiting conflicts with the principles of khozraschet management and turns out to be an active lever of economic control in the management system. This concept of redistribution is influenced in a major way by certain factors, i.e., primarily by:

--the ways in which funds are generated for redistribution and the rules governing their allocation;

--the determination of the order by which financial resources are allocated for redistribution (profits, depreciation allowances) in organizations that generate funds for redistribution;

--the determination of the amounts of funds slated for redistribution;

--the determination of the areas in which these resources will be used.

It goes without saying that at individual levels of management these factors will play different roles (in terms of redistribution within the ministry framework, redistribution within the VHJ framework, and so on).

In this article we will be talking about the problems associated with the generation of financial resources, and in order to illustrate these problems we will be analyzing concrete empirical data for individual VHJs in the jurisdiction of the Federal Ministry of General Engineering and for the ministry as a whole covering the period 1976-1978. Based on our analysis of these figures, we will attempt to come up with some conclusions and recommendations which might help to make the utilization of the financial levers of economic management in the engineering industry more efficient.[3]

We will use the volume of financial resources and the structural breakdown of their formation and allocation as a point of departure for our assessment of the importance and effectiveness of the use of economic management levers in the area of branch-ministry finance policy.

The volume of financial resources generated by the Federal Ministry of General Engineering [FMVS] during the period 1976-1978 is shown in Table 1 below.

Table 1 was compiled in a way that enables us to break down total revenue funds into funds received from the national budget, the VHJs and directly managed enterprises and concerns, and within this framework the table also shows the breakdown for types of revenues.

In a certain sense and by way of analogy we can regard the funding received from the national budget as "outside" funds and the other two categories of funds as "internal" resources.

Table 1 shows that most of the funds available to the FMVS come from internal sources (the actual ratio for 1976 being 71.5 percent, 78.6 percent in 1977 and 25.6 or 91.9 percent[4] in 1978), which goes to show that this branch ministry has a solid foundation on which to conduct its own active financial policy.

The other tables reproduced below show how these funds were allocated and are therefore a concrete reflection of this policy.

Of the three most important spending categories (i.e., profit-margin subsidies, working capital subsidies and capital investment subsidies) it is mainly the last two that reflect the specific planning goals of the branch ministry and are indicative of its managerial role.[5]

Table 1. Revenues of the FMVS During the Period 1976-1978 by Types

(in percent)

	(6) období	(7) státní rozpočet (8) předpoklad	(9) skutečnost	(10) VHJ předpoklad	skutečnost	(11) podniky přímo řízené[a] a koncerny předpoklad	skutečnost	(12) celkem podle druhů předpoklad	skutečnost
příděly ze státního rozpočtu (1)	1976	100,0	100,0					26,5	28,5
	1977	100,0	100,0					20,4	21,4
	1978	—	—					71,7[b]	74,4[b]
odvody ze zisku (2)	1976			20,6	21,3	59,6	60,3	18,0	18,3
	1977			25,0	24,9	64,9	63,8	22,3	22,0
	1978			32,3	25,8	51,6	50,9	9,5	7,1
ostatní odvody ze zisku (3)	1976			—	—	—	—	—	—
	1977			0,3	0,3	0,6	0,6	0,3	0,3
	1978			—	—	—	—	—	—
odvody na vrub fondů (4)	1976			27,6	30,9	17,6	16,9	19,5	21,0
	1977			22,1	23,6	25,2	22,1	17,7	18,6
	1978			27,3	31,7	23,9	24,2	7,7	8,0
odvody odpisů (5)	1976			51,8	47,8	22,8	22,8	36,0	32,2
	1977			52,6	51,2	9,3	10,1	39,3	37,7
	1978			40,4	42,5	23,8	24,1	11,1	10,5

a) In the Czechoslovak economy concerns are in fact a type of VHJ, but they are considered to be separate institutions for statistical purposes and we are taking this distinction into account in this article.

b) The high percentage figures for national budget appropriations during 1978 are the result of the granting of special government appropriations to be used as interim loans in 1977 that were recorded in financial statements for 1978. The fact that these special appropriations were made is a highly unusual case. If we subtract from national budget appropriations the amount granted in the form of interim credits, the percentage of revenues coming from this source is reduced to 8.1 percent.

Redistribution of Branch-Ministry Financial Resources Among VHJs as an Integral Part of the Funding of VHJs

The financial resources of a branch ministry (in our case the FMVS) which are drawn upon by that ministry as a means of conducting its financial policy in relation to its subordinate enterprises still account for only a portion of the total funds that are used to influence the financial position of the VHJs.

The VHJs receive funds not only from their superior organ (branch ministry), but also directly from the national budget, and most of their funding comes from the latter source as is shown in Table 3 below.

Table 3. Subsidies Granted to VHJs (in percent)

(6) total

At the same time, however, Table 3 documents the increasing contribution of the branch ministry to the total funding of the VHJs during the period 1976-1978. The size of this contribution has increased sharply especially in 1978. Nevertheless, the appropriations paid out to the VHJs by the FMVS are still smaller than the appropriations from the national budget.

At this point several questions naturally come to mind. Namely, is this an ideal situation in terms of the apportionment of the management workload in the managerial hierarchy of the Czechoslovak economy? What were and what are the reasons for this funding pattern? Is it a good idea to keep doing things this way, or would it be advisable to act on proposals calling for the modification of this system?

A long-range, specialized study in the area of economic theory and practice will have to be completed before we can come up with a thorough answer to these questions. And it may be that even then the answers will be inconclusive, rather they may have to be qualified by taking into account the then prevailing level of development of productive forces and relations at the then given stage of our socialist economy.

Nevertheless, we will try to provide some answers to these questions. In the first place we will have to make a more thorough analysis of the aforementioned statistics before we can come up with any answers to these questions. Accordingly, we will focus our attention on the trends revealed in the way these funds are allocated to the VHJs, trends which are illustrated by Table 4 below.

An examination of Table 4 reveals that the largest appropriations of funds to the VHJs during the period under review were intended to be used for capital construction purposes, i.e., 64.2 percent of total appropriations during 1976, 67.4 percent in 1977, and 83.8 percent in 1978, while the average for the whole period was 71.8 percent. We have included the categories listed under items a), d) and h) in the figure for total capital investment subsidies.

a) This table was compiled on the basis of the exact figures for appropriations from the national budget and from the FMVS to VHJs and their subordinate enterprises during the period 1976-1978.

b) VHJs report all capital investment subsidies, including both those received from the national budget and those received from the FMVS, with the exception of capital investment subsidies received from state revenues and from the sectoral and ministerial account for the redistribution of depreciation allowances.

c) VHJs submit figures on the fixed limit of funds received for the reimbursement of invoices recording the fulfillment of tasks provided for under the terms of the state or ministry plans covering research and development work and also figures on the actual reimbursements received and chargeable to these fixed limits. The plan target figures cited here refer to the financial plan.

d) This refers to capital investment subsidies received from the sectoral or ministry capital construction fund and from the ministry account for the redistribution of depreciation allowances.

e) This refers to capital investment subsidies received from state revenues, subsidies which do not fit into the above categories a) and e) and for which separate provisions are made in the financial plan.

f) This refers to subsidies received for the fulfillment of enterprise and sectoral research and development projects and for the support of the activities of research and development organizations or offices.

[key to Table 4]

(13) subsidies derived from both redistribution and state revenue accounts
(14) wage fund subsidies
(15) Red Banner subsidies
(16) planned
(17) actual
(18) 3-year average

Another large share of these appropriations was supposed to be spent on scientific and technological research and development work in support of the fulfillment of tasks assigned by state or sectoral authorities, i.e., 12.8 percent in 1976, 15.6 percent in 1977 and 11.4 percent in 1978, whereas the planned ratio for the latter year was 17.8 percent. These percentages represent the sum total of appropriations under items b) and e).

Miscellaneous profit margin subsidies (item c) accounted for 12.1 percent of total appropriations to VHJs in 1976, 5.4 percent in 1977 and only 2.3 percent in 1978. On the average these 3 categories of subsidies accounted for 91.2 percent of all appropriations made during this period.

The structural breakdown of the subsidies granted to the VHJs is a reflection of the varying degrees to which the management of individual areas has been centralized. In a socialist economy central organs are most concerned about the management of capital spending and technological development.

These areas of economic activity have always been a prime concern of our highest ranking state and party organs. In this connection it is also interesting to analyze the priorities assigned to the appropriation of funds to VHJs from the branch ministry and from the national budget.

This analysis has shown that subsidies paid for out of the national budget are concentrated mostly on the funding of capital construction. These subsidies are covered by the 2 items listed in Table 4, i.e., capital investment subsidies and capital investment subsidies derived from state revenues, which in 1976 amounted to 71.0 percent, in 1977 to 75.3 percent and in 1978 to 80.4 percent of total subsidies paid for out of the national budget.

If we evaluate the structure of these funds, we will find that they were supposed to be used for two main purposes, i.e., for capital construction and as miscellaneous subsidies to funds for redistribution within VHJs. In percentage terms these appropriations can be described as follows (see Table 5) (the sum total for all subsidies = 100 percent):

Table 5.

(in percent)

	(3) plán			(4) skutečnost		
	1976	1977	1978	1976	1977	1978
dotace na investice (1)	46,8	46,9	83,2	41,5	43,0	87,7
ostatní dotace k zisku (2)	38,1	25,3	5,0	28,8	21,7	4,8

Key:

(1) capital investment subsidies
(2) miscellaneous profit margin subsidies
(3) planned
(4) actual

The figures given in Table 5 clearly show that there was a positive trend toward a decline in the share of miscellaneous profit margin subsidies during the period 1976-1978.

An analysis of the individual subsidy categories also produces some interesting findings. On the basis of this analysis it is possible to reach some indirect conclusions as to the focal point of the branch ministry's work in this area.

Table 5 shows that most subsidies received from the national budget are concentrated in the capital investment area. In terms of absolute amounts the capital investment subsidies paid for out of the national budget during the years 1976 and 1977 were 6 times greater than the same kinds of subsidies paid for with FMVS appropriations. It was not until 1978 that the capital investment subsidies paid for out of the national budget and out of the budget of the FMVS proved to be more or less equal. Considered solely from this standpoint, this would mean that either a majority of these capital spending projects exceed the bounds of the ministry's jurisdiction or that the ministry's involvement in this area is minimal. Is this a desirable situation? After all, the Federal Ministry of Finance [FMF] and the FMVS are both central agencies which are charged with the

responsibility of promoting the fulfillment of general public needs and uniform government policies. A branch ministry's overall responsibility for promoting the development of the industries in its jurisdiction should also encompass the exercise of control over capital investment policy, including control over the expenditure of funds allocated for the purpose of implementing this policy.

We believe that the distinctions made with regard to the methods used to finance capital construction should not be viewed in strictly procedural terms, rather it is important that we should also acknowledge divisions of authority and responsibility among branch ministries and central agencies with economy-wide jurisdictions. It would seem that in recent years (witness the figures quoted above) some initial steps have been taken toward putting this principle into practice.

The subsidies allocated by the FMVS to the VHJs in its jurisdiction are concentrated in two main categories, i.e., capital investment subsidies and miscellaneous profit margin subsidies.

We have already discussed subsidies for capital investments. The other category of subsidies actually represents a kind of "balancing" mechanism used by the superior organ on behalf of its subordinate organizations. These subsidies are supposed to compensate subordinate organizations for lost profits, losses which are the result of decisions made by higher authorities. These losses are in the interest of the ministry as a whole, but in the short run they may have an adverse impact on the profitability of subordinate VHJs.

Under no circumstances should these subsidies be used solely in order to place poorly managed and well-managed VHJs on an equal footing. In our view the branch ministry should have complete control over the allocation of these subsidies. But in 1976 the national budget played a rather major role in the allocation of these subsidies, i.e., in that year subsidies financed out of the national budget accounted for 81.8 percent of all subsidies allocated by the FMVS. Even though it is obvious that the point of all this is that we should put a stop to undesirable interventions in the profit-and-loss situations of the VHJs on the part of central authorities, the authority for making these interventions should be confined to the responsible branch ministry, and this organ should have complete control over the marshaling of funds for the payment of these subsidies. The validity of this principle is substantiated by the analysis that was made of the relevant statistics for the next 2 years. In 1977 the contribution of the national budget to these subsidies amounted to only 5.8 percent, and in 1978 it contributed no funds at all to these subsidies.

On the other hand, the subsidies paid for out of the national budget under the heading "fixed-limit funds for the reimbursement of costs related to the fulfillment of tasks provided for under the state scientific and technological development plan" are entirely justified, even though this claim

does not appear to be overly warranted in light of the funds actually allocated for this purpose during 1976 and 1977. But during 1978 we witnessed a noticeable improvement in this area.

The financial policy of the FMVS vis-a-vis its subordinate VHJs, taking into account the position of the VHJs and their general directorates as mid-level management components in the engineering industry, is graphically illustrated by Table 6 below. To some extent this table also describes the position of the trust-type VHJs and their general directorates together with all of their inherent problems.

Table 6. Subsidies Allocated to VHJs by the FMVS (in percent)

		(4) plán			(5) skutečnost		
		1976	1977	1978	1976	1977	1978
GŘ VHJ	(1)	70,4	73,5	68,1	90,4	79,6	60,9
podnikům VHJ	(2)	29,6	26,5	31,9	9,6	20,4	39,1
celkem	(3)	100,0	100,0	100,0	100,0	100,0	100,0

Key:
(1) VHJ general directorates
(2) VHJ enterprises
(3) total
(4) planned
(5) actual

Table 6 clearly shows that the branch ministry's finance policy toward the trust-type VHJs governs both its relations with the VHJ general directorates and, in a direct way, with VHJ enterprises.

This situation is similar to that which prevails in the case of relations between the national budget and branch ministries and in a direct way between the national budget and the VHJs that fall within the jurisdiction of this ministry.

We believe that this situation is to some extent also the result of the ambiguous economic position of VHJs, primarily trust-type VHJs, in the Czechoslovak economy.

These problems, though the most important are those that pertain to the relationship of the national budget to the VHJs and directly to the enterprises that comprise these VHJs (in principle these problems are one and the same), problems which at the present time have been partially resolved through the experiment on efficiency and quality management, are still indicative of a certain degree of vagueness in the status of the branch ministry (and hence indirectly in the status of the system of economic branch management) in the Czechoslovak economy and, at the same time, of problems plaguing the so-called middle management level of the economy.

From a strictly economic standpoint it would be reasonable to conclude that all funds allocated by the branch ministry to VHJs should be channelled

into their general directorates. However, Table 6 shows that this is not the case. The end uses of funds allocated by the FMVS to VHJ general directorates and directly to their subordinate enterprises are revealed by figures deduced from an analysis of the hard statistics for the period under review (see Tables 7 and 8).

Table 7. Most Common Spending Categories of Funds Allocated to VHJ General Directorates (in percent)

		1976	1977	1978
(1)	dotace na investice	45,9	38,2	86,9
(2)	ostatní dotace k zisku	30,7	27,2	7,9
(3)	dotace na doplnění obratového fondu	16,2	9,2	—
(4)	dotace na ostatní prostředky fondů	4,—	1,1	2,8
(5)	dotace na úhradu plánované ztráty	—	14,3	0,29

Key:
(1) capital investment subsidies
(2) profit margin subsidies
(3) subsidies for supplemental deposits in revolving fund
(4) subsidies for miscellaneous capital funds
(5) subsidies for the reimbursement of planned losses

Table 8. Primary Uses of Funds Allocated Directly to VHJ Enterprises (in percent)

	1976	1977	1978
(1) limit prostředků na úhradu úkolů státního plánu rozvoje vědy a techniky	65,4	25,4	7,02
(2) ostatní potřeby účelově financované	17,1	—	0,01
(3) dotace na investice	—	42,32	19,46
(4) dotace na investice z redistribuce	—	—	69,07
(5) dotace na Rudé prapory	—	19,37	0,14
(6) dotace z redistribuce a z fondů	—	10,76	—
(7) ostatní dotace k zisku	11,0	—	—

Key:
(1) fixed-limit funds to reimburse costs associated with the fulfillment of tasks provided for under the state scientific and technological development plan
(2) miscellaneous earmarked funding requirements
(3) capital investment subsidies
(4) capital investment subsidies derived from redistribution
(5) Red Banner subsidies
(6) subsidies derived from both redistribution and state revenue accounts
(7) miscellaneous profit margin subsidies

The figures cited in tables 7 and 8 can be referred to to point out some interesting facts and to draw certain conclusions.

First, it is evident that, with one exception (capital construction during 1977 and 1978) funds were allocated to the VHJ general directorates for different purposes than the subsidies paid out by the ministry directly to VHJ enterprises.

Second, it is apparent that the subsidies allocated by the ministry directly to the VHJ enterprises during the years under review covered a wide range of spending categories.

The question arises as to whether these findings are desirable and what kinds of conclusions should be drawn from them.

It is our belief that the first finding can be welcomed as a positive development. The reasons for this assessment are as follows.

The funds channelled into the VHJ general directorates are the result of the redistribution of central revenues at the ministerial level in conformity with ordinance No 151/75 of the government of the CSSR.

These funds are used as subsidies for VHJ sectoral funds, and the relevant general directorate is legally responsible for overseeing the management of these funds and, wherever applicable, their redistribution to subordinate enterprises.

The assessment of the second finding will be somewhat more complicated. The funds allocated by the ministry directly to VHJ enterprises have a dual nature. On the one hand, we are talking about funds for strictly earmarked accounts, while, on the other hand, we are talking about expenditure categories which allow some leeway for the selection of alternatives. In the first case the VHJ general directorates obviously have no say in how these funds are to be spent and their direct allocation to VHJ enterprises is justified. This is primarily in reference to items 1, 2, 3 and 5 as listed in Table 8. In the case of the final spending category [item 7 in Table 8] we are, of course, dealing with a situation that is analogous to that described above (the relationship of the national budget to the VHJs), since the reasons for granting these subsidies have to do with the falloff of enterprise profits as a result of decisions made at the ministerial level. Nevertheless, it is our view that the VHJ general directorates should have complete control over the allocation of these funds. Therefore, we believe that these subsidies should be channelled into the VHJ general directorates.

Similarly, when it comes to those categories of expenditure which involve the redistribution of financial resources (per items 4 and 6 in Table 8), we believe that by their very nature they ought to be ranked among those subsidies which are allocated by the ministry to the VHJ general directorates.

If in reference to the above table we compare actual values with projected values, we will find that our conclusions and theoretical assumptions on this score are, in fact, substantiated by economic experience (represented by actual figures), frequently in contrast to plan projections (the exception being the 1978 capital investment subsidies derived from redistribution accounts). We also analyzed the impact of the national budget and the branch ministry on the financial position of individual VHJs in the jurisdiction of the FMVS during the period 1976-1978. This analysis too provided us with some interesting findings which supplement our analysis of the role of the branch ministry in the management system of the Czechoslovak economy.

For example, it is interesting to note that the VHJs ELITEX AND CHIRANA, i.e., the only two concern-type VHJs in the FMVS, are included among those VHJs which received the smallest subsidies during this 3-year period. In 1976 they received the lowest subsidies of all, while in 1977 they were among the 4 and in 1978 the 3 least subsidized VHJs.

At any rate, it is impossible to say whether the relatively superior "self-sufficiency" of these VHJs is a result of the establishment of the new concern-type VHJ, whether this "self-sufficiency" necessarily paved the way for the transition to concern-type VHJs, or whether it is an outgrowth of other circumstances. The only way to explain this is by making a further detailed analysis of the management practices of individual VHJs.

Assuming that the first hypothesis turned out to be correct, then from the standpoint of financial management this might tend to lend support to the acceleration of the process whereby the trust-type VHJ is being transformed into a concern-type VHJ and at the same time uphold the spirit of the comprehensive experiment which is bringing the management practices of the trust-type VHJs closer into line with the management practices of concerns, especially so in the financial area.

It was also interesting, for our purposes, to analyze the channels through which funding appropriations make their way from the FMVS or the national budget to individual VHJs, funding channels which lead both to the VHJ general directorates and directly to their subordinate enterprises. At the same time, we must, of course, remember that the total amount of funds going to the VHJ general directorate amounted to 29.9 percent in 1976, 34.7 percent in 1977, and 41.7 percent in 1978 of the funds transferred directly to VHJ enterprises from the national budget and from the FMVS.

This analysis revealed that during the period 1976-1978 VHJ general directorates received funds from the FMVS and the national budget according to the following percentage ratios (see Table 9 below).

Table 9.

(in percent)

	1976	1977	1978
z FMVS	90.8	76.7	98.2
ze státního rozpočtu	9,2	23.3	1.8

Key: (1) from the FMVS (2) from the national budget

These percentage relationships are completely reversed in the case of VHJ enterprises (see Table 10 below).

Table 10.

(in percent)

	1976	1977	1978
z FMVS	2,1	6,8	26,3
ze státního rozpočtu	97,1	93,2	73,7

Key: (1) from the FMVS (2) from the national budget

These figures are a reflection of the current status of trust-type VHJs, i.e., at a time when, as far as financial relations are concerned, the national budget maintains direct ties with VHJ enterprises as state economic organizations and separate direct ties with VHJ general directorates, which are also classified as state economic organizations. These figures also reflect the positive trend represented by the growing influence of the branch ministry in controlling the financial policy (and influencing the financial position) of subordinate VHJs (including both VHJ general directorates and VHJ enterprises).

This positive trend has already been encouraged in a decisive way by the comprehensive experiment in efficiency and quality management, in accordance with which the VHJ has consistently been regarded as a discrete economic entity regardless of its organizational and legal forms. This conclusion is fully substantiated by the findings of our studies.

The underlying principles of the Set of Measures for Improving the Planned Management System of the National Economy After 1980 also call for the building up of economically powerful VHJs that conduct all of their business in accordance with the principles of khozraschet management and also maintain relations with the national budget that are consistent with their status as discrete economic entities.

Conclusion

In light of what has been learned so far from economic theory and practice in the area of economic management it follows that during the years that lie ahead, especially so during the Seventh Five-Year Plan, it will

continue to be necessary to address ourselves to the task of insuring the uniform and comprehensive impact of all economic planning levers geared toward encouraging the fulfillment of qualitative performance indicators related to the capital replacement process.

In this article we have made certain recommendations aimed at improving the management of financial policy at the branch ministry level. We have been discussing for the most part problems associated with the development of VHJ financial resources in relation to their redistribution at the branch ministry and national budget levels. To be sure, this is only one aspect of financial policy. In a future article we would like to discuss the related problems of developing financial resources at the ministerial level and current problems of profit taxes in relation to the financing of capital construction.

2. Law No 62 (SBIRKA ZAKONU, 26 October 1977) on Revisions in the System of Organizational Levies and Taxes.

3. The following tables were compiled on the basis of figures taken from the statistical reports of Min. Uc. [expansion unknown] 7A-04, VHJ Uc. 6A-04 and Uc. 4A-04.

4. See footnote (b) for Table 1.

5. To some extent this also applies to profit margin subsidies, since to a certain extent these subsidies are intended as compensation for the consequences of branch ministry decisions which might have lessened the profitability of specific subordinate VHJs, but which were necessary in the interest of the ministry as a whole. Moreover, the profits earned by a VHJ also have an impact on its working capital and capital investment requirements.

VHJ AS BASIC MANAGEMENT LINK EVALUATED

Prague HOSPODARSKE NOVINY in Czech 15 Aug 80 p 3

[Article by Jaroslav Kratochvil, J D: "The VHJ (Economic Production Unit)--Basic Management Link"]

[Text] The gradual transformation of the VHJ into a basic management link is associated with two interconnected processes. In the first place it is the formation of the VHJ as a comprehensively equipped and internally specifically integrated economic unit, and it is also the transformation of external conditions and relations of the VHJ to its politico-economic milieu, such as organizational, socioeconomic, legal relations, etc. Even though the formation of a whole framework of legal forms of the VHJ and the corresponding position of enterprises are important and certainly necessary, it must constantly be emphasized that the legal form alone does not of itself deal with the essence of the transition of the VHJ into a basic management link, because the decisive factors are the actual forms of management and their gradual transformation in the spirit of the principles applied in the current stage of development of productive forces. Connected with this is a great number of problems to be dealt with.

Problems, Opinions, Experiences

So far, neither in theory nor in practice has the position of the socialist enterprise been fully clarified, since it is ceasing to be an enterprise in the (relative) concept of an independent legal entity. Some economists admit that we do not yet have a sufficiently universal and precise designation for the enterprise as an economic category. This gradually evolving new type of enterprise will more and more be characterized by its social integrity, manifesting itself in ever greater involvement with the whole organism of the national economy, and thus not at all in its detachment as an "independently" operating unit. To be sure, problems are arising whose solution goes beyond the bounds of the enterprise. To effectively direct the socioeconomic development of society it will be ever more necessary to solve problems of matter, space and time which considerably surpass the dimensions of institutional systems organized up to now.

VHJ - Enterprise Relations

Although for several years now the process of transition to larger economic production complexes has been proceeding in all the socialist countries, the chief reason for their emergence was the solution of problems of central management, rather than the actual organization of a technical production base. That is also why the majority of various forms of VHJs usually resulted from one-time reorganizations, and mostly on the sectoral principle of homogeneous production. Even that is, to a certain extent, not a very stable basis, because with certain developments in techniques and technology the relevance to the homogeneous sector could change substantially.

I am of the opinion that, in spite of this definite tendency, we should continue to foster, within certain bounds, the concept and position of the enterprise and we should not disregard it, because the enterprise usually has very important relations with local bodies and all its surroundings which cannot always be fully replaced by "new" relations to the economic production complex. At the same time, the management of especially remote VHJs must, even with a societywide approach, deal with certain problems connected with local conditions; although even practical aspects of the management of large units dictate that certain operations will have to be left to the enterprise.

It must also be realized that with the growing number of conditions requiring the formation of their own management systems it is impossible to find specific, well-defined organizational solutions, especially with regard to legal forms. These conditions directly call for even greater diversity of the actual management structures.

Practical experiences of development up to now show that the fixed and customary concept of the management mechanism as a sum total of single bodies responsible for every specialized management function will no longer suffice, and that it will be necessary, even in spite of certain definite advantages of the functional approach, to gradually go over to a goal-oriented program of management. Thus the result will be that the object of management in the VHJ will not be mostly individual enterprises, as is largely the case now, but rather the focus of management will be shifted over to the basic and conceptual problem complex of the entire integrated VHJ. At the same time, however, it is necessary to see that the solution of ever more complicated problems of the economy does not intensify the mutual separation between individual units, and particularly that the management of economic complexes does not split off from the production base and subordinate organizations.

The gradual transition of the VHJ's organization of its management system and mutual relationships into a basic management link will be carried out be degrees so that it will correspond to the necessary changes which can realistically be made in people's thinking, especially that of supervisory workers of the enterprises, because existing organizational structures

(and especially the fading concept of the enterprise as a basic management link of the enterprise sphere) are deeply rooted in the conscience of the people and are also associated with certain prestige prositions, social standing, pay allocations, occupational specialties, etc.

It is not always easy to overcome the steady influence of existing organizational systems one has become accustomed to and persuade working collectives and individuals not only to passively accept the new organizational arrangements, but even to take the initiative in inculcating them into people's thinking. That is why the transition of the VHJ to a basic management link (especially in concern organizations) also calls for timely political-economic and social-psychological preparation, systematic instruction of all workers about the reasons for and goals of the new organizational setup, and the changes in actual forms of management.

It must be admitted that so far the economic sphere has not had an adequate conception of the essence and depth of changes associated with the transition of the VHJ to a basic management link (especially from a trust form to a concern form of VHJ). The essential activity of general management must be directed toward the VHJ as a whole (not, that is, above individual enterprises). The administration of the general management of the "new" type of VHJ will not take over the activities which independent enterprises have performed up to now, but rather will deal with new tasks of a higher order, assuring high levels of efficiency in all work which the individual enterprises would not even have been capable of by themselves. Thus it would also be absolutely wrong to try to contrast the strengthening of the VHJ as a basic management link with the full utilization of the activity and initiative of enterprise collectives and intraenterprise units, because the VHJs and the enterprises must work on qualitatively distinct, though mutually complementary, levels of managerial and organizational work.

We must guard against critical observations indicating that with the standards of certain VHJs their current style of management does not solve material or specific problems, but only shifts them over to other management links, so that the VHJs are becoming places where tasks are written out and assigned administratively, often without any essential differentiation, rather than being really effectively and comprehensively dealt with. However, there should be an objective investigation to find the causes for the subjective shortcomings and inefficient forms of management, whether perhaps they are due to the general system of management or whether the general management of the VHJ has the material, cadre and financial resources to meet its new assignment.

Basic Objective

Let us, therefore, try to identify at least the main principles of the basic requirements and activities which the actual VHJ management as a basic link, must carry out:

--First of all, ensure consistent orientation toward the criterion of social efficiency;

--Goal orientation--that all processes taking place in the VHJ are directed toward the goals which are based on overall developing trends with due consideration for the actual status and potential of the national economy;

--Application of scientific-technical developments as the basic source of efficiency and future development and acceleration of the innovative cycle aimed at ensuring global standards of production and high quality of products and export capability;

--Closer and more purposeful systematic integration with the international division of labor;

--Increased flexibility and adaptibility, which means reacting promptly to changing conditions of world markets and anticipating future changes in advance;

--Fulfilling the integrating function of the VHJ in order to prevent the development of individual areas of activity in an isolated manner without mutual consistency;

--Purposeful and balanced division of authority and responsibility, especially in relations with subordinate enterprises and the conditions created to centralize critical activities (in practice one of the most difficult problems);

--Improved utilization of the human factor and effective motivation, together with the development of informal participation of workers in management;

--Effective and closer association of the handling of problems of social development of the collectives with economic development.

In spite of this clarification of the basic objective of the VHJ as a basic management link (as opposed to its former position as an intermediate management link) the concept of the VHJ as a basic level of management is not yet clearly enough formulated either in theory or in practice. But it can be said that it is that organizational level where the necessary material resources and authority capable of ensuring the development of basic factors of production are concentrated, where economic processes are directed comprehensively, and where objective conditions are developed for finalizing production, even on the level of the VHJ, where socioeconomic indicators of the plan are transformed into technical-economic indicators and composite indicators are transformed into forms of enterprise management, and where supplier-consumer relations are concentrated possibly to their original status.

Therefore, in assessing the overall work of the VHJ we cannot go only on the basis of fulfillment of plan indicators, even though that is an

important political and economic objective, but rather we must consider the criteria of substantial improvement and intensification of conceptual and prognostic activity, the efficacy and comprehensiveness of the management of investment, technical, commercial, financial and personnel policies, greater continuity and flexibility in supplying the national economy and fuller integration of social and economic development. Another important aspect is efficiency of management processes within the VHJ.

Application of Khozraschet Principles

The 15th session of the CPCZ formulated for the general management of the VHJ as a basic management link the specific task of consistently applying the khozraschet principles and a system of norms, costing and budgeting, especially in the area of intensification of intraenterprise management. This, however, did not involve any new requirement because these principles have been included in a number of documents, since the very beginning of the management of socialist industry. But it will not do to simply talk about these questions, especially in general terms. Every VHJ must immediately, according to its specific circumstances, proceed to develop and apply the khozraschet principles as a natural part of current working obligations so that the results will be accessible to every worker.

And it is precisely in the practical application of the khozraschet principles of management at individual organizational levels and in their full utilization that general management has not yet carried out its task, especially in the direct (not only methodical) management of integrated subordinate units. In this connection it appears that, with respect to concern forms of VHJs, the method of handling the concern khozraschet has not yet been fully clarified, especially the relationship between the VHJ khozraschet as a whole and the khozraschet of individual concern enterprises. We can also consider as inadequately settled the important problem of effective stimulation of concern enterprises with respect to results of the entire VHJ as well as the actual fulfillment of planned objectives.

We must also not overlook the mutual connection of forms of management of VHJs and enterprises with the development of organizational structures of the actual technical production base of industry. Even though since 1945 we have gone through several mass reorganizations, it can be said that up to now no profound analysis of the production structure of our entire industry has been made and that in essence they have been based on the sectoral principle. These one-time organizational changes involved the concentration of organizational functions and a greater or lesser centralization of certain management functions which lacked practically any character of concentration of production. That is why even at this point certain no longer desirable chance situations and aberrations persist in the actual organization of the production base and the ensuing organizational relationships (a considerable imbalance even of certain VHJs and especially enterprises, a large number of small enterprises, plants and separate operations).

Whereas economists and theoreticians in nonsocialist countries are forever seeking the best or even "ideal" organization, nothing like that is being attempted by either the theoretical front or in practice in socialist countries. That is to say, here we maintain the necessary dialectical-materialistic approach toward seeking optimal organizational forms and the corresponding styles of management as a matter of continual development and progress connected with the expansion of the material base and productive forces of the socialist community.

Experience so far with the transition of the VHJ to a basic management link indicates, however, that even with the existing legal basis in the form of the concern or sectoral enterprise, it will undoubtedly be quite a long process, depending particularly on the creation of conditions for a basic change in existing forms of management. It also appears necessary to examine more closely and evaluate the relationship between the size of the economic production complex and effective forms of their management from the point of view of exercising practical control, a factor which cannot be underestimated for attaining optimal operational results. This depends on a precise definition of the extent of necessary general or operational activity in order to prevent dilution of the conceptual comprehensive management functions of the VHJ. According to the concept of the VHJ as a basic management link, operational activity should be performed here only -

--if it is required to implement societywide interests;

--if it is necessary to support the integrity of the VHJ system of management;

--if it facilitates more efficient performance of certain (especially joint) activities at the VHJ.

The Influence of Legal Forms

The requirement set forth at the 15th session of the CPCZ that the VHJ become a basic management link undoubtedly corresponds to current trends of organizational development in all socialist countries. It must, however, be stated that this transformation of the VHJ was at first primarily connected with the question of the most suitable legal form of the VHJ for which the sectoral enterprise, and particularly the concern one, was designated. Experience has shown, however, that the essence of the shift of the VHJ to a basic management link depends primarily on a basic change in management forms and a more effective mutual division of authority and responsibility among the ministry, general management and the enterprises according to the various specific conditions of individual sectors.

It was also gradually recognized that with a certain modification of the legal form of the trust (such as that with experimental VHJs) the trust, too, could become, also with a certain change in its management system, a basic management link (particularly with the broad spectrum of the sector

or diverse character of subordinate units). It could be characterized thus--that with constant pressure to raise management standards in order to achieve full efficiency the enterprises should probably reach the level of the former well-managed VHJs, while the VHJ as a basic management link should, from a societywide and comprehensive point of view, go over to a qualitatively higher form of VHJ management as a whole.

The intent of this article was to point out the urgency of solving a great number of problems concerning the position of the VHJ. In this connection the provisions of the Set of Measures for Improving the Planned Management System of the National Economy After 1980 are welcome suggestions since they incisively clarified the position of the VHJ as a basic management link and the corresponding position of the enterprises. At the same time this problem complex is considered also from a necessarily different objective and time interval.

SOCIOECONOMIC COMPONENTS, CONTRADICTIONS OF STRUCTURAL CHANGE VIEWED

Budapest KOZGAZDASAGI SZEMLE in Hungarian No 7-8, Jul-Aug 80 pp 797-813

[Article by Jozsef Bognar, director of Research Institute for World Economy: "Socioeconomic Components and Contradictions of Our Structural Change"]

[Text] The 12th congress of the MSZMP raised to the rank of national action that economic policy conception which matured in the course of past years concerning a structural reordering of the Hungarian economy. Its maturation was made possible by a careful analysis of the external and internal situation and of the economic relationships which represent possibilities for and limitations on rational economic action, and by the conclusions and debates which followed this analysis. The credibility of some of the more radical conclusions was reaffirmed by those negative results and experiences which the economic leadership achieved or acquired by their habitual or symptomatic treatment of the new problem world which has developed since the world economic change of epoch. The signs are that this shock effect was needed in order for the economic leadership to be able to break with a few conceptions and methods, which have been overtaken by time, which in the preceding decade still represented a source of many economic achievements and successes.

Naturally this economic conception has not yet been transformed into a program encompassing an action system and mutual relationships and effects which would solve (from above!) all of our developmental dilemmas. (In any case it is probable that it is not possible today to prepare a medium-range program which would solve every dilemma "from above." But even if it were possible it would not be rational because on the basis of uncertain hypotheses it would tie up too much economic energy and thus would make difficult an adaptation to the changes in a period in which development has accelerated and the effects on us of events cannot yet be known clearly because their effects have multiplied.) The resolutions of the congress, however, indicate those basic principles and behaviors (individual, enterprise and economic leadership behaviors) which constitute preconditions for restoring the balance and for a more advantageous adaptation into the world economy. The resolutions have stressed certain

fundamental goals and preferences to which other action--in so far as economic conditions make it possible--must be adjusted. The congress adopted as useful and progressive in regard to the future those methods and components of economic thinking and analysis--supplementing or replacing earlier ones--which constitute the value judgments needed for formulating the conception. Finally, it established and emphasized that the rational action system included in the conception--which arose from an objective analysis of real economic relationships--represents even theoretically a further development in the self-development of the socialist society and economy (appearing in the form of concrete relationships).

It is well known that the development of a new economic policy conception was made unavoidable by a number of developments and requirements which appeared simultaneously and involved both similar and contradictory effects. I would like to stress three of these centers of effect or motivating forces.

Concerning the Intensive Type of Economic Development

A switch to an intensive type of economic development has become necessary and even unavoidable. Such a switch can be initiated even at a time when the extensive type still functions relatively satisfactorily but when a careful and profound scientific analysis indicates that we have already passed the peak. From the economic viewpoint this moment is the most favorable for the gradual introduction of changes but difficulties are caused by the fact that economic policy public opinion is not yet convinced of the unavoidability of the change and so resists it or holds it back. The switch could have had this character here if we could have grown into the present "reform epoch" by an organic and gradual expansion of the frameworks of the mechanism reform.

In the present situation, however, neglecting the switch would lead to economic collapse because due to the prolongation of the extensive growth type and in the course of it there have arisen balance deficiencies which cannot be liquidated in this form of growth, indeed they are created anew in an expanded form. The intensive growth type, however, has different driving forces and so the movement system of the society and of the economy must be ororganized in such a way as to permit the implementation of these driving forces. Of these driving forces we should mention needs satisfaction requirements (instead of a shortage economy), the technical development, rationalization and innovation tied up with structural change and the external economy.

Experience proves persuasively that needs satisfaction is not only a quantitative and qualitative problem but also an organizational problem of an economic policy nature because the vertical profile of our producing enterprises is unjustifiably narrow and to a large extent operations and activities suitable for offering services are missing from the economy. Such a situation could develop because the economic organizations here were built

up "downward" exclusively from production and never "upward" from needs (the market and sales). Similarly, the technical development tied up with structural change and a swift product change demands not only a transformation of the "product structure" but also presupposes substantial social policy changes.

It must be emphasized in connection with external economic factors that they play a growth encouraging role in every economy now, from the side of both import and export. The Hungarian economy was not sufficiently prepared for this organizationally. Since the world economic change of epoch, which extraordinarily strengthened the system of mutual dependencies and determinations among economies, the system of interdependence, we will have to develop in our economy capabilities and properties in regard to our link to the world economy which only "competition economies" have had thus far in the development of economic history.

(The reference to "competition economies" means that, as in the past, socialist economic science rejects that interpretation of competition according to which it is an automatism of the economic cycle which selects among economic units in the interest of the common good. Since the second half of the 19th century such an interpretation of competition or of a competition economy has changed even in capitalist economies because counterpoles to free competition [cooperatives, associations, trade unions, etc.] and organizations striving to put an end to competition have come into being.)

There can be no doubt that with the development of the socialist economy in past decades the idea of the unavoidability and even positive nature of competition has won ground in connection with supplying the populace with consumer goods.

The increasing significance of external economic factors brings up the necessity of providing to our economic undertakings on the world market those conditions and supports on the basis of which they can compete successfully with those undertakings behind which stand the flexible mechanisms of the capitalist economy.

Concerning the Effects of the World Economic Change of Epoch

The world economic change of epoch represents and will represent in the future also the second center of effect. By world economic change of epoch I mean the totality of those epochal, fundamental economic and non-economic (demographic, social, political, scientific, international, etc.) changes which will decisively influence the living conditions and economic circumstances of mankind in the decades ahead. Of these fundamental and epochal (long-range) changes I am thinking primarily of such things as the new relationship between man and nature (a symbiosis on the basis of modern science and technology), the limits and uneven distribution of natural resources in an interdependent and very sensitive world, the problems of feeding the world (in the form of an approaching crisis), the danger of technology (for the first time mankind has a technology with which it could

destroy the conditions for its own existence), the arms race which takes the form of "mutual terror", the backwardness of international political and economic relationships as compared to the general interdependence and problems of a world scale, etc. We can say without exaggeration that even in the decade just behind us mankind entered the spoch of extreme alternatives.

These enormous changes are not only economic ones; they extend to the entire area of human-social and international relations. This will mean a new scientific challenge and it will gradually mature new modes of thinking. This is absolutely necessary because if we relied on our old methods and our old knowledge we would be incapable of adequately understanding the new relationships.

Naturally certain components and manifesting forms of these enormous, epochal and fundamental changes already appear in present economic relationships. Let us only think of the price explosion (price revolution) and of inflation as persistent phenomena of the economies appearing in a new form, of the serious balance deficits, of the decrease in the rate of growth, of the shortages appearing in resources, of the increasingly anarchic phenomena of the international financial system, of such threats to international economic contacts as the American embargo and similar things.

The long-range and fundamental effects of the world economic change of epoch also mean for us that in the course of conversion to the intensive development type we can develop only goals (or goal systems) which are in harmony with the requirement system of the change of epoch and we can select only those methods and forms of action aimed at attaining them which are not antagonistic to this powerful requirement system.

The Problematics of the Balance Deficit

I want to mention the economic balance deficit as the third of the centers of effect. Several factors have contributed to the development of the balance deficit, including:

--the circumstance that in the course of the economic cycle we generate a greater demand than we produce the conditions (assets) for satisfying it;

--the overestimation of the ability of the state budget to bear the burden;

--the swift growth of import needs in the course of switching to the intensive development type;

--the development of the international terms of trade in a way unfavorable for us; and

--the lag behind what is required of capacity suitable for economical export production.

There is a unique action system to put an end to the balance deficit. In the beginning the factors of the necessary action are more or less of a limiting character because putting an end to the deeper causes generating the balance deficit requires a longer time and coordinated action. The unavoidable limitations must be applied with great circumspection and after careful consideration lest our temporary regulations hinder the development of those energies, capabilities and capacities with the aid of which the balance could be restored over the longer run.

Weighing, on the one hand, the extraordinary importance of the internal and external interests attaching to a more perfect functioning of our own society and economy and, on the other hand, the elemental strength, intensity and persistence of the currents flowing from the great centers of effect mentioned, it is obvious that our tasks in connection with a structural reordering of the Hungarian economy are extraordinarily great and complex.

What is involved is not a simple switch-over or the elimination of merely temporary problems; rather, what is involved is a radical transformation of the functional, action and guidance system of the Hungarian economy so that it should be capable of a flexible accommodation to the swift changes of uncertain sign which can be expected later. It is obvious, however, that transforming the functional, action and guidance system of the socialist economy to adapt to the new requirements is not only an economic question but also a social, political, cultural, scientific and ideological (systematic) problem.

The Present Phase of Reorientation as Compared to the 1968 Reform

It could be especially instructive to compare the breadth, depth and substantive problems of the social actions necessary to realize the present economic policy conception to the factors set in motion in the course of the 1968 reform. In the economic history sense our economic reform of 1968 was of outstanding significance in the history of socialist management.

This reform gave full recognition to the significance of economic relationships as opposed to a conception of the economy which was projected from a vision (a vision of the future). (Let me note only in parentheses that it thus gave back the true object of economic science--an analysis of real economic relationships and interdependencies. It is thanks to this that since 1968 Hungarian economic science has achieved even internationally recognized results, has developed new methods and encouraged the development of schools.) It was also an important starting point that it replaced the hierarchic system of individual interests' group interests and general social interests with a conception of interests in which these types presupposed and complemented one another thus making it possible, under appropriate economic conditions, for individual and group interests to become driving forces for the realization of the common interest. There was also significant effort to put an end to the shortage economy and to satisfy needs more fully by means of competition and material interest. Special

mention must be made of that sphere of measures which the reform took in the interest of economic undertakings for only within this framework did the enterprises become economic units instead of branch departments of the ministry.

One could continue at length a list of the achievements of the 1968 reform, but this is not the subject of this study. There can be no doubt, however, that the 1968 reform deliberately concentrated only on the problems of the economic mechanism (the guidance system) while it affected questions of economic policy or the institutional system only indirectly. There were decisive political reasons for this. Later, many criticized the "one-sidedness" of the reform, pointing out that it would have been more correct to introduce a more complete reform (embracing economic policy and the institutional system as well). I do not want to start a debate with the critics; but the idea that the introduction of a more complete reform would have been more correct does not mean that in the situation at that time the introduction of such a reform would have been possible or even useful. (Let us only think that after 1968 the scientific efforts and preparations taking place in the interest of economic reform (froze solid for a few years everywhere!)

What is now essential from the viewpoint of a comparison is that the action zone and depth of the present economic policy (strategic) conception will be substantially greater than that of the 1968 reform and the changes to be expected will extend to economic policy (including foreign economic policy) and to the institutional system too. Even by itself entering the intensive epoch means economic policy changes but the requirements of the world economic change of epoch also strengthen the quantity, intensity and quality of the necessary economic policy changes. Because of the external economic character of the new economic policy conception--which is strengthened by the new circumstances (for example, the increased interdependence) defined by the world economic change of epoch--the abilities, foresight, flexibility, decision and reaction speed, etc. of our institutional system will become part of the economic competition taking place on the world market. I will return to this question in this study; in this place it is enough to emphasize that under such circumstances a reform of the institutional system can no longer be postponed.

I would like to point out one more essential difference in connection with a comparison of the 1968 economic reform and the present economic policy conception (which has been accepted in its basic principles). The "degree of freedom" of the 1968 reform was much greater because we had to contend with fewer constraining factors. The economy was relatively balanced--although the balance was at a substantially lower level--we did not yet have any significant foreign debt, our foreign economic dependence was smaller, our supply of energy and raw materials seemed assured, the world economy still enjoyed its "golden age." At present, however, we can rationally choose only the economic policy conception formulated in the guiding principles; our alternatives are to be found within this conception.

The Transformation of the Basic Principles and the Guiding Principles into Social Action

The chief task in guiding a socialist society and economy is to transform the various basic principles, guiding principles and aspirations, taking into consideration the interest relationships and structures and with an awareness of the real social-economic relationships and the trends to be expected in the future, into an interdependent system of social movements which will finally lead to attaining the desired goals.

But in the course of outlining the social-economic movements we must always reckon with the fact that the relationships socially created and the relationships economically desirable do not coincide. The reverse is true also--it can be imagined that a different sort of economic relationships and situations might be more desirable from social, political, security, cultural or ideological points of view.

When working out action programs, however, a full awareness of the real social-economic relationships is needed and these relationships must be analyzed in their dynamics. In every sort of political system the social-economic relationships have more flexible components capable of greater changes and they also have more static, more conservative and more rigid elements. Naturally, these factors deriving from the real relationships must be taken into consideration when working out action programs.

The question arises: Is contemporary socialist economic science capable of transforming the various scientifically founded basic principles and aspirations into a system of social movements while taking into consideration the interest relationships and structures?

The best abilities and methods of economic science find expression in a system of adequate information about economic reality, relationships and interdependencies. Naturally, the relationships, circumstances and situations themselves change too and thus their nature, character, effect and linkage systems are transformed also. Experiences become more numerous, methods of examination are refined (this refinement takes place in the internal workshops of science) and there are changes in the world surrounding the economy. But these changes do not change the fact that the primary goal of economic science was and is a recognition of economic relationships in the dynamic sense.

This knowledge--as in the case of other branches of science--is abstract (to put it more precisely, it has the character of being abstractable); that is, it starts from the hypothesis that only economic factors influence economic relationships and processes.

(It is well known that the starting point in political economics--in contrast to this conception--presupposes a basic analysis of political, social, cultural, etc. factors too. But the practice is different. In recent decades there has hardly been a work in economic science which examined the

economic situation in conjunction with politics, the capabilities of the social structures which have developed or the concept of public opinion in a dynamic way, in the midst of action.)

From the viewpoint of action this hypothesis is of an abstractable character, but it has great significance; for it means that economic relationships can be changed only with the aid of methods which are in harmony with these relationships. This statement is of special significance in the case of political systems known for their desire for action, their optimism and their strong value systems because they are often inclined toward a "transformation" of the economic relationships dynamically interpreted by means of administrative (state administrative) methods which usually leads to the development of serious economic situations and the forced actions which follow therefrom.

This is not a new phenomenon historically because the development of the modern economy was preceded by centuries in which there were not yet any independent economic relationships. The first economic theories (cameralism and mercantilism) felt that intervention in economic life by the state using non-economic (administrative-power-public administration) methods was necessary and rational. Classical economic science was born in the intellectual struggle against these ideas; classical economics attributed self-regulating forces to the internal movement relationships of the economy which led to the realization of the common good.

According to our conception, however, intervention and guidance are needed in addition to an adequate knowledge of the economic relationships. In the event of intervention and guidance, however, an adequate knowledge of the economic relationships is not sufficient because economic and non-economic factors are mixed together in the real conomic processes and phenomena. In such a case the economic phenomena do not appear in their original forms; they have other properties, effects and abilities to receive effects. For this reason contemporary economic science, and even more so the economic science of the future, must move on to multi-disciplinary methods, for without these guidance and influence are not possible.

The activity groups (state, social, security, cultural and ideological) mixed with the economic phenomenon world have their own conceptions, value relationships and (within the structure) institutional centers. These conceptions, values and (institutional) interest relationships can further or hold back or reverse the realization of economic policy conceptions. Thus, the approach to economic problems on an interdisciplinary basis must give an answer to the question of whether the movements and behaviors characterizing the institutions and activities most interdependent with the economic conception will further or hold back the realization of the economic policy goals.

To speak more precisely and more practically, is it possible and in what way is it possible to transform the movement of the various activities, institutions and value systems so that they will aid and further one another, solve similar tasks in a more co-ordinated and more cooperative manner

(for example, the problem of intensive department means a new situation and new requirements not only for the economy), harmonize in time and in content their mutually supporting efforts and mitigate the possible conflicts? These requirements prove that it is not enough for economic science to become multi-disciplinary; it is also necessary for the other branches of science (legal and state science, sociology, defense policy, educational policy, ideology and science policy) to find linkage points leading to the economy. They must strive with common and coordinated research, a harmonization of conceptions, debates and agreements to concentrate the actions of the various sciences and institutions on the attainment of the chief social goal or goal system.

In what follows I would like to illustrate with a few examples what sort of clashes and conflicts could be caused by the economic policy conception adopted in the resolution of the 12th congress and what transformations are made necessary in order to transform the basic principles accepted into social movements. I would like to emphasize, however, that the clashes and conflicts are potential ones, that is, they can be mitigated in the event of rational action by those interested. In our structure conflicts among conceptions are generally "hidden" because those participating in the action can follow the "customary" (previous) logic and reflexes of their institutional system without anyone objecting or taking exception to it. But conflict does occur--by the nature of the matter--if one of the actors proceeds in a customary but obsolete way.

Clashes and Conflicts in the Course of the Transformation

It is difficult to "discover" conflicts because most people feel that customary action is conflict-free a priori and in general, although such a judgment depends on the situation and the time.

Clash Between Ideology and Economic Policy Aspirations

At the time of the socialist transformation ideology represented a form of the political struggle against the internal and external enemies. After the building up of the socialist society and the development of its structure ideology can become a form for recognizing and analyzing reality which encourages society to recognize new problems and solve them in a modern way. This possibility has not been realized here, for which there are various reasons--connected with the peculiarities of our development. Since the ideologists and other theoretical experts had not developed a picture of the present on the basis of an analysis of concrete relationships but rather by projecting on the present various elements of a picture of the future it was obvious that the renewal of socialist economic science (after 1953) had to take place without them, indeed with their silent or vociferous resistance. In what followed an antagonism and mutual distrust arose between the economists striving for a concrete analysis of economic relationships and the ideologists who were building a present out of a picture of the future; it followed that some of the theoretical experts were

inclined to recognize as ideologically justified only the changes which had already taken place. The situation was made worse by the fact that the non-economists (political, security, cultural and council experts) got their economics culture from this stratum.

The antagonism which has arisen between the economists starting from an analysis of economic relationships and the cultivators of theory largely frustrated or made possible only at the cost of much loss of time the introduction of economic reforms which were due. It is obvious that in a "competition economy" we cannot permit ourselves the loss of time which would result if a reform could be introduced only when the conservative (rigid) solutions have precipitated a shock effect by their partial failures. I would like to emphasize that we are anxious not only and not even primarily for the reforms, because according to experience they must be realized in any case as soon as the solutions opposed to the economic relationships fail, at least in the form of a crisis.

It is primarily the socialist economy we are concerned about lest, as a result of clashes within its structure, much time is lost in an epoch when competition (the critical situation) is again putting the national economies to the test and when development has so accelerated that the loss of a few years could be fatal.

Clash with the World Economy

In what follows I want to deal primarily with those clashes and problems inside and outside of the economy which are connected with the inclusion of the Hungarian economy--and naturally those of the other European socialist (CEMA) countries--in the world economy from the export side. (In earlier articles I have already noted that this inclusion from the import side already took place in the 1960's.)

Fitting into the world economy from the export side is a difficult economic and social problem in itself because it makes necessary the discovery of new energies and driving forces and the development of new capabilities. Today, however, this fitting in must be realized in the complex, contradictory and uncertain condition system of the world economic change of epoch.

Adapting to the new world economic conditions is a complex task even for those technically and scientifically developed countries with great material resources and reserves which are not only included in but even influence the world economy.

We must calculate that due to the brake on the dynamics of economic growth the growth in foreign trade and in imports will slow down around the world. As a result the competition for markets will sharpen to an extraordinary degree. Two types of economic strategy danger threaten us, the Hungarian economy, in this competition. The first danger consists of the

fact that the technical development of the capitalist countries and the transformation of their scale of needs will be faster than the improvement in the modernness of our export structure and export products. This would mean that the profitability and economicalness of our export would stagnate or decline. This situation, naturally, would mean a deterioration in the terms of trade since the prices of fuels and raw materials will increase further--with cyclic variations and temporary price reductions arising from over-speculation--and the most developed technology will be increasingly expensive because the producers of it will be striving to make up the losses they suffer in the import of energy and raw materials. The second danger consists of the fact that the developing countries are making great strides on the world market--especially in the export of finished products. This process is justified economically even if it sometimes takes extreme forms. But it is possible (or more precisely, it can be imagined) that this conquest will take place--in part--at the cost of the socialist countries. The objective conditions for this are given because the affected part of the population of the developing countries making advances in the export of industrial articles is learning rapidly, they have or can easily obtain the raw materials, costs are lower (due to the low level of wages), and the developing countries enjoy many preferences on the markets of the developed capitalist countries.

Naturally, in the event of a clever and active trade policy the potential competitors could become cooperative partners.

But it is questionable whether we can find the organizational and cooperation forms which would be sufficiently advantageous for both sides (to be more precise, more advantageous than other possible solutions) and offer sufficient protection against the consequences of temporary political tensions and cyclic changes.

Concerning the External and Internal Components of World Market Competition

World market competition extends to very many types of interdependency, including:

--recognizing (forecasting) in time the needs, situations and possibilities and decisions which will transform the recognition into social-economic action;

--the technical level, quality, prices, variety, the primary materials used, the abilities and experience of the labor force, accommodation to the special needs of the customer, delivery time limits, reliability (reputation), follow-up supply, service and other services;

--marketing (sales) innovations. (I think that it is not necessary to prove that innovation, the modern and the backward, are possible in marketing methods too and that marketing methods have a strong effect back on production.)

If world market competition extends to so many types of factors and interdependencies and if our economic development depends to such a significant degree on its development then it is obvious that the real competition takes place not only in regard to goods and services, prices and quality, modernness and accommodation to the needs of the user (customer) but also between those national economies the dynamic capabilities of which are reflected by the aforementioned goods and services. Under socialist circumstances this interdependency is open and direct; in the case of capitalist countries it is more transposed and less direct. (In this study I do not want to go into an analysis of the differences and deviations in connection with this because they do not affect the message and conclusions of this study.)

Speaking of national economies I am not thinking in this connection primarily of the material goods created thus far and accumulating in the course of development but rather of those dynamic capabilities the level of which is reflected by the goods and services appearing on the world market. I mentioned dynamic capabilities because great significance must be attributed to the tasks set by situations and requirements because it is obvious that there must be a harmony between capabilities and tasks. The dynamic capabilities of national economies derive from a broad background; they include those components, interdependencies and mutual effects of social, political, cultural and ideological capabilities which are connected to the economy.

In addition to the significance of interdependencies and mutual effects one must also emphasize that naturally the capabilities mentioned have functions, situations and effects which are independent of the economy too, and vice versa; components which are not "purely" economic play a substantial role in the development of the capabilities of national economies. But the interdependencies and mutual effects are not limited to those cases where the capabilities mentioned (social, political, cultural and ideological) are put into motion in connection with economic questions; they also exist (in an indirect form) at times and in situations where these capabilities are being expressed within the framework of their own immediate functions. It is also obvious that the goals, tools and structures created to take care of the immediate functions also have an effect on the social fitting in of the economy. Naturally social activity is a substantially broader and more complex concept that the economy because a society also has non-economic functions, movement systems and aspirations. But it is obvious that the basic principles and structures, or the concrete movements thereof, adopted by society in the form of the political system, have, in the interdependencies and mutual effects of social activities, a strong influence on the place and role of the economy in society. The education and training system has a great effect on the abilities and preparedness of the labor force; the guidance and decision system defines the zones and frameworks for economic movements; the order and development of scientific research influence the innovation capabilities of the economy. It is obvious that the level of development and the zones of the information systems influence the ability of the economy to survey the expected development of world economic processes.

The foreign policy movement scope of a state and its place within the international political system substantially influence the foreign economic possibilities of each national state.

These references to interdependencies and mutual effects--far from complete--also prove the correctness of the proposition that national economies participate in world market competition not only on the basis of economic capabilities and processes in the stricter sense. Via the economy or via the effects (mutual effects) on the economy the competition is participated in by all those social, political, cultural and ideological activities (factors) which set or influence the frameworks, zones and conditions of the economic processes. This proposition should be supplemented by noting that different economic power relationships and developmental levels stand behind the competitors appearing on the world market. It is obvious that a small country with relatively limited economic strength--having a small share of the market--is not able to influence world market conditions or supply-demand relationships, is not able to acquire new markets or offer to its customers the advantageous credits needed to force out competitors. From the strictly economic viewpoint undertakings or economies at a middle technical level have a disadvantage to start with as compared to their competitors with greater economic and technological power. They must make up for these disadvantages in those spheres and activities which are in large part not strictly economic. These include greater flexibility, which depends on the action zones guaranteed to the economy; the ability to make speedy deliveries, for which suitable free capacity and swift decisions are needed; better preparedness and capabilities of the labor force, which depend on the education system; better innovation capabilities, which depends on the information flow of society. On the basis of what has been said it is obvious that in strengthening the competitiveness of the Hungarian economy greater significance attaches to the non-economic components of competition than is the case for countries and undertakings which are economically stronger.

Factors Endangering Our Competiveness

In what follows I would like to speak about a few components of the functioning of our economy and of the social condition system defining it which especially endanger our competitiveness in the world economic or world market sense.

a. As is well known, our economic organizations were formed in a period when we did not yet have sufficient experience, when we did not yet know the nature of socialist economic relationships and when, as a result, the projection of the picture of the future still played a crucial role in the development of the organizational forms. The projection of the picture of the future was accompanied by an underestimation of commodity, money and market relationships and by a schematic interpretation of the role of production. As a result the economic organizations which were created were centered on production; they did not recognize needs, the market, the

marketing possibilities as the starting point for economic organization; they were organized horizontally (and not vertically). In addition, there has been a revolution in the theory and practice of economic organization in recent decades which, naturally, was only accelerated by computer technology.

Thus one of the crucial conditions for maintaining or improving our competitiveness is the development of organizational forms which are in harmony with modern organizational principles, technology and marketing methods.

b. We excessively tie down production capacity at the beginning of the (medium or short-range) economic periods. This phenomenon is interdependent in part with the shortage economy psychosis and in part with a schematic (false) interpretation of planning and economic security. Shortages lead to the logical seeming conclusion that all capacity must be used to a maximum in order to overcome them. But this argument would stand up only if capacity and needs coincided. But in our case a significant part of the shortages can be attributed to the fact that we do not have economic organization units and forms suitable for satisfying the broad range of demands on the service and commodity market. The full burdening of production capacity makes the economy inflexible and insensitive to changes. In addition, there is an attempt to more completely burden capacity not only in regard to plants producing finished products (assembly plants) but also in the entire vertical structure producing semi-finished goods, subassemblies and parts.

It is obvious that foreign economic organizations backed by such an inflexible production background cannot be capable of flexibly satisfying world market demand (adjusting to the competition in delivery times and other respects).

c. As a result of the state guidance of the economy our decision making system is slow, through-put times are extraordinarily long, the decisions are made at a very high level far from the real economic processes and there is much parallelism and duplication in them, which washes away the responsibility not only of the individuals participating in the decisions but also of the institutions. After the beginning of the plan period the organs making the decisions do not have at their disposal either real material assets (credits and capacity) nor manpower. According to their subject the decisions are economic ones but according to their motives they are not because the organizations making the decisions are not acting under the influence of economic relationships; they do not have the interest, they cannot make a profit, they do not undertake risk, and at most they have only a moral interest in the outcome. It is obvious that such a decision making system does not aid but rather holds back the work of those economic undertakings which must participate in the world market competition. For this reason the decision making system must be re-examined--keeping in mind the economic requirements and conditions.

d. In the past the political-ideological requirements and the expectations of public opinion encompassing and influencing the economy did not always ensure to the economy the movement scope needed for rational action. In the course of our economic development thus far the rational action (naturally in the dynamic sense) based on economic relationships was not always in harmony with the various political-ideological requirements and social expectations. These requirements and expectations derived from a projection of the future and not from an analysis of the economic relationships and possibilities. These requirements and expectations represented limitations, prohibitions and forced situations for economic action. Thus, in the course of development, there often occurred steps which were hurried or which went beyond the real possibilities--from the economic viewpoint--and these produced deficits, balance problems and "lost profit" (profits which were missed).

(Most recently this has happened primarily when cautious economic leaders, fearful of a temporarily or locally unfavorable political judgment, postponed taking steps which could have led to considerable profit.)

From the nature of things there are there will be in the future "politically sensitive zones" for economic action. But it would be a serious mistake to think that in the event of a clash or apparent clash of political and economic interests the economy must automatically give way and make concessions--under the consolidated social relationships. In a consolidated society political aspirations can be successful only if they are economically well founded and supported. On the other hand, in the event of balance deficiencies and the inadequate functioning of the economy the needs of the populace and of the economic cycle cannot be satisfied and sooner or later this will lead to political complications.

In our day the opinions and ways of thinking about the relationship of politics and the economy are more realistic but for this very reason we must remember that there will be politically sensitive zones for economic action in the future (in the decades ahead) so it seems proper to predict and clarify these problems and situations--with the aid of appropriate scientific research.

Concerning A Few Non-Economic Components of Economic Development

In conclusion I would like to talk about a few non-economic factors of economic development. If our relationship to the economy is to come closer to what is desired there is need for a rethinking of the possibilities and limitations hiding in the nature and movement system of the non-economic factors too.

There is an especially burning need for such an approach today when economic development has become so complex and contradictory, when epochal changes are taking place in the world economy and when the dependence of our development on that of other economies has reached a magnitude never before known.

Among these factors I would like first to touch on questions interdependent with the state guidance of the economy.

The abolition of the direct plan directive system represented a gratifying turn in the relationship of economy and law; from the nature of things this system had placed the coercive elements of the law in the foreground. Since then we have found that the more developed (and more complex) relationships which have been created have given room for a more progressive interpretation and functioning of the law. (Naturally, I am thinking of legal questions interdependent with the economy because this is interdependent with what I have to say.) But to a significant extent the guidance of the enterprises is realized amidst state administrative forms--via regulations. It is a peculiarity of the situation that we--unlike other socialist countries--do not have middle level guiding organs. At first approach these middle level guiding organs appear desirable economically because in this way the regulation of economic processes would be realized via economic organs. From the side of law this situation is called "decentralization." But if we go more deeply into this interdependency we see that the middle level guiding organs embody a very great, bureaucratic--monopolistic--economic power and not only do they endanger enterprise independence but also they prove slow and clumsy in satisfying needs, in adapting to changing conditions, in flexibility and in the speed of their decisions. In addition, they are not built "upward" from the economy but rather are built "downward" from state administration.

There can be no doubt, however, that state guidance of an accelerated economic development and model oriented toward the world market raises many objective problems. In the present situation, and in the decades ahead, we can only start from the following:

a. the economy today is a source not only of possibilities but also of internal and external dangers;

b. in this situation not a single essential question can be solved with the old approach; and

c. the guidance, leadership and decision making system must adapt to the nature and situation of the economy and to the requirements of competiveness.

Starting from these basic principles it seems justified to re-examine the relationship of state guidance and the economy, making use of joint scientific efforts and interdisciplinary methods. The question arises: How can one, indeed can one at all separate statehood, in the political and economic sense, so that the decision making and guidance system will accommodate to the nature of the economy while maintaining the unity of the state or statehood?

The Tasks of Education and Training From the Economic Viewpoint

It is well known that in certain areas and tasks labor and capital can rationally replace one another. Foreign studies prove that there is a weak

correlation between productive ability and intelligence. It is obvious that in countries poor in capital and raw materials a highly qualified labor force (that is, one with the best capabilities) can have an especially great role in structural change, in technical development and in adapting to the international economic circumstances. It must also be noted that building up mechanized systems for certain intellectual work, operating them according to needs and possibilities, understanding complex world economic interdependencies and surveying the interdependencies and mutual effects among various activities require more not only quantitatively but also qualitatively.

These requirements suggest that it would be justified to review in a comprehensive way our education and training system from the economic viewpoint (that is, from the side of social needs).

The social-economic role of education can be formulated in different ways. There are those who stress that the diploma (the training) is proof of having acquired professional knowledge and gives one title (the right) to filling higher level positions. Others--this is a rare formulation in socialist countries--regard education and training as a selection (filtering) tool even if the selection is not tied to excessively high or firm requirements. I feel that the most modern formulation, the one most useful from the viewpoint of society, is that the chief task of education is to develop those abilities and talents which will make it possible for the members of society to be able to act and live rationally with the accelerated development amidst the increasingly complex political-economic relationships. The development of abilities and talents represents the only humane and rational possibility for a highly trained labor force to renew itself and others in thinking and behavior through four decades (the time served after winning a diploma) amidst the conditions of accelerated development, the swift obsolescence of information, the increasing social mobility and the change of generations which is accompanied by significant tensions. This also means that it is not useful to choose a career too early (at the age of 14 years) and that we must build within the school system channels which link one system to another.

Special care must be given to the free unfolding of abilities. The socialist society and economy will need more and more creative talents who think independently, and understand the relationships surrounding them in order to overcome their historically inherited backwardness and adapt in a modern way to the changes of history, world politics and the world economy.

Naturally the education of talent cannot be the exclusive viewpoint in a socialist society and education system. In addition to ensuring equal opportunity care must be taken--for humanitarian and necessary reasons, in accordance with the nature of the system--to protect and aid the weaker. An atmosphere made more creative by those with talent can help even the mediocre to rise to a higher level.

In any case, from the viewpoint of the economy it must be emphasized that it is not possible to stand one's ground in the economic competition without creative, enterprising experts ready to take risks and thinking in a combinative manner!

A New Place for Science in the Social Structure

The role of science must be conceived of in a new way in a system of new economic and social structures and needs too. No longer can the taks of science be limited to the mere development of knowledge, explaining and interpreting the situations which have developed or proving the coherence of various theories. Its chief task is the preparation of action systems serving the interests of society. There will be much greater need to carry out this task than there was earlier when sensible routine actions could still be useful. Now we stand before an age in which we must approach the phenomena and interdependencies which have developed in a creative spirit because they differ from former ones in their components and effects. Cooperation in the preparation of action systems--as I have already said in my comments on economic science--will require the development of interdisciplinary methods, not only among the several branches of the social sciences but also between the social sciences and the natural sciences. In the solution of social-economic problems one must always consider the entire range and effects of problems extending from the symbiosis with nature through the geological location of raw materials to the increasing application of technology. In addition, the utilization of the achievements of natural science and technology raises very many social-economic problems which appear not only in the industrial branches (economic branches) cooperating in their application but also in problems interdependent with the fundamental operational conditions and order of value of society and the economy.

Taking into consideration that we must maintain ourselves in the world economic and world market competition and the fact that the conditions for so maintaining ourselves depend primarily on science, we come to the conclusion that in the decades ahead science must play an orienting, renewing and creative role.

It must know, directly and indirectly, the needs of society and it must help in planning the actions directed at improving the situation. It must also be noted that thousands and tens of thousands take part in action; as a result of this we must build up new channels for transmitting information lest a gap arise between science and public opinion which cannot be permitted in a democratic society.

It must also be noted that the propositions and conclusions of the social sciences serve the interests of all society but often, even in a socialist society, they clash with developed or even rigid structures, well established particular interest relationships, which are protected by a combination of power and ideological methods. This circumstance always

represented a disadvantage to the cultivators of the social sciences whereas everyone (including the power and the structures) regarded the discoveries of natural science as useful--since the industrial revolution. (In part this was interdependent with the fact that they did not yet recognize the social effects of the natural science-technical discoveries, or felt them to be distant in time.)

So everything must be done in the interest of the freedom of social science research because otherwise we may be 5-10 years late with the introduction of every new factor and this cannot be permitted under present international and economic circumstances.

Society and the political leadership must see clearly what can be expected from science. The dialectic of social-economic development proves that there is no "problem-free" society. The solution of every mature problem is accompanied by the appearance of new problems. The greater our knowledge, the more interdependencies we recognize; so action becomes more complicated. Increasing knowledge and development are accompanied by increasing uncertainty; progress has dangers and risks. This very complex situation, however, requires greater responsibility and cooperation from science.

So realizing the economic policy basic and guiding principles outlined by the 12th congress will require great and coordinated efforts from scientific research, from the economy and from the institutions which influence the situation and movement system of the economy. We are coming to face the problematics of a mature socialist society which wants to achieve a higher degree of development, taking into consideration the requirements of world economic competition. But solving the complex problems and interdependencies of a mature socialist society requires not only and not even primarily enthusiasm and optimism; rather it requires understanding, expertise, a comprehensive knowledge of relationships and value systems, a many-sided overview of international economic interdependencies, creativity, an enterprising spirit and similar things.

But the economic action program in the process of formation is sober and realistic in the sense that it is clear about the possibilities and the limitations on action. There are no unlimited possibilities even in a socialist society, although it was believed that there were in that romantic age which led into terror. The possibilities in the economy are never unlimited; if they were there would be no need for management. Goals must be set in the interest of development (although even these limit one another) and the goals must be compared with the means available, which can never be limitless in this finite world. We do not have to be "chagrined" because of the limits--whether they be the limits of the economy or the limits of the political power--because without limits there is no rational action. I believe that the present stage of self-awareness, the maturity of the socialist society, the comprehensive knowledge of our relationships and the abilities and readiness of society provide a foundation for renewal so that we can hope for the realization of the great national action program which has been mentioned.

ENTERPRISES FINDING COOPERATIVE SOLUTIONS TO INCREASE PRODUCTIVITY

Budapest NEPSZABADSAG in Hungarian 16 Aug 80 p 3

[Article by Judit Kozma: "Productive Associations"]

[Text] "Do it yourself if you don't have a servant," goes the saying, and, seeing its wisdom, we are sometimes obliged to undertake tasks which we would much rather entrust to professionals. However, if they are simply not available, for example, if the electrician has promised to come five times and never comes, what else can a man do: join the "Do It Yourself!" movement. It will probably be done less skillfully, and in addition will take longer to do, but at any rate it will be done.

If all of this happens with a simple citizen, it can be disregarded. But if the "Do It Yourself" movement offers industrial enterprises the only possible route to finish certain work, it can cause a great deal more concern.

Conspicuous Backwardness

Still, a good many enterprises are unavoidably forced to do this. After all, uninterrupted production unconditionally needs, for example, components, machinery, and work performance which can simply not be ordered from anyone. Or, if there were such a possibility, he would not make shipments in time or not in the necessary quantity and quality. If by chance someone accepts an order, he will refer to the economy of large-scale production and will only be ready to sign a contract for several times the needed quantity.

However, the absolute lack of assurance of contractual ties and definite services inevitably forces the enterprises to become equipped for activities which do not fit their profile. For example, they are forced to produce cogwheels, bolts and axles, and more than once to prepare special components, to repair carts, to wind coils, and this series could be continued for a long time.

Naturally these are very detrimental situations. Actually in the majority of cases the proper industrial background, production techniques and expertise are lacking for side activities of this type. Work of this sort is thus not so much production as "makeshift" in which more than enough men are really kept busy, so that production is considerably impaired.

The international comparative inspection, which the heavy industry enterprises carried out in 1976, unanimously showed these consequences. In the first place they showed that the production of our domestic plants is considerably behind the leading enterprises of the industrially developed countries, by a much greater extent than the Hungarian industrial technical level and technical equipment would justify.Among other things, it is very clear that our backwardness is not primarily in direct production processes, but rather is striking in the production servicing areas. For example, a comparison of the Hungarian-GDR chemical industries will show this graphically. In the GDR approximately 55-60 percent of the enterprise staff participates in the direct production process, while 40-45 percent provide the other service activities, shipping, maintenance and other work. In our country the proportion is the reverse of this, and the proportion of those performing direct productive work is relatively small.

Promising Programs

Thus, it is not so much a lack of modern technology which is lying hidden behind the production differences, since our most productive factories produce just as many products with a much larger staff than the foreign enterprises serving as a base for comparison, but rather the improper organization within the enterprises and the ties between enterprises.

These observations have established the 10-year programs to raise production, developed by the heavy industry enterprises. The enterprises set up the goal of reaching the current leading international production level by 1985 at the latest. According to calculations the time portion of the program has materialized, and although the development of the enterprises has naturally not been of an identical extent, altogether in 1980 30,000 fewer are working in this branch, compared to the original calculations of the fifth 5-year plan. Along with this the activity of a number of enterprises, including the Bakonyi Bauxitbanyak, Dunai Koolajipari Vallalat and Tiszai Vegyi Kombinat, was striking, and is already approaching the best foreign factories today.

Most of this is due to the fact that the enterprises took seriously technical and organizational solutions, and assigned an important role to those things by means of which the personnel demands of production could be reduced and the special auxiliary processes could be better organized. For example, a good number of enterprises, with the assistance of foreign organizers, have significantly increased their productivity, and in many places have developed wage systems to stimulate better production, have applied ingenious small machinery and have implemented effective innovations.

Something has happened in almost every enterprise, and heavy industry is no exception to the general phenomenon. These methods have been mentioned at various exchanges of experience, but the majority of them have continued to remain outside the factory gates, although their application elsewhere would have brought a great deal of utility.

Naturally there have been exceptions. For example, some enterprises have established maintenance cooperation, within the framework of which they help each other with personnel, machinery and equipment in the case of peak repair times or unexpected deficiencies. Cooperation between bauxite and coal mining has also been successful. The use of the chamber-face methods applied in bauxite mining increased productivity in coal mines of a similar nature to a large degree. The lack of similar initiatives by themselves do not markedly interfere with an increase in productivity, but these few examples do show that there are very large reserves in closer collaboration between enterprises.

Let Good Methods Spread

Recognition of this fact led to the implementation of a specific organizational form in heavy industry: the productive association. The first was established on the other side of the Danube 1 year ago with the cooperation of 16 heavy industry enterprises, 2 foundry and machine industry enterprises, 2 construction enterprises, research institutes and the Veszprem Chemical University. The second came into being 1/2 year ago in Budapest with the participation of 16 enterprises, while the third was established in the recent past in the northern Hungarian areas. The last is worthy of special mention because the narrow branch barriers were successfully crossed here, and 16 plants belonging to other departments joined 12 heavy industry enterprises.

This specific development of enterprise cooperation was also aided by foreign experience. Organizations which regularly follow the development of productivity attentively and help in raising the productivity of enterprises are coming into existence in almost every developed country. The European Association of National Production Centers regularly reports on productivity, and this was a good point of departure for specifying the technical area of domestic associations and for developing their organization.

On the basis of voluntary participation the productive associations organized have undertaken a wide range of tasks, with due attention to foreign experience and naturally to domestic needs and possibilities. For example, they regularly follow the development of the international and domestic level, make comparative inspections, take part in developing scientific methods and spreading them, and in general strive in every possible way to encourage closer connections between enterprises.

One of the most obvious possibilities is the acceptance and spread of successful methods worked out in individual enterprises. There have been many examples of this in the past year. Not only have the enterprises studied the so-called event-oriented maintenance method, which reduces maintenance time and expenses by 10-15 percent, developed in the Szekesfehervari Konnyufemmu, but a number also want to implement it. A great deal of interest was shown in the conference dealing with a review of four kinds of wage systems, organized in the association on the other side of the Danube. In more and more places they are reviewing and applying experience in energy economy, and Taurus, for example, will achieve an energy saving of about 300,000 forints in the second half of this year by applying technical control methods developed within the association framework,

But there are not only applicable methods in other places, but useful equipment can also be found elsewhere in individual enterprises. For example, the Koolajipari Gepgyar is buying a plasma-cutting machine which will then be jointly used by three other factories. Thus these three enterprises will avoid buying the machine, and the owner will be able to operate the machine more economically.

"Let's Do It Together!"

Of course for all of this it is necessary to know what is needed, or what the possibilities are in another enterprise. Thus in the Fejer megye the Bauxitbanyak and the Bakony Muvek "became acquainted." The result was the Multicar mine vehicle. The bauxite mine and the Autokozlekedesi Tanintezet developed the vehicle together. It requires little room, is manueverable, self-loading, and suitable for carrying both freight and personnel. In this way it can be used, not only in mines, but in enterprises, as a material-handling machine. However, the Bauxitbanyak in the Fejer megye was unable to undertake the production, but the Bakony Muvek had the necessary conditions, and it is already in large-scale production.

There are also less striking results of mutual acquaintanceship. For example, the Egyesult Vegyimuvek handed its unused and superfluous scaffolding equipment over to the Budapesti Koolajipari Vallalat, where investment work would have slowed down without it. The Vegyepszer, the Kobanyai Gyogyszerarugyar, the Dunai Koolajipari Vallalat and the Egyesult Vegyimuvek transferred various iron sheets, tubes and collecting elements worth 300,000-400,000 forints to one another, and assisted in their maintenance. Aid of this type rendered daily is at least as significant for the association work as the form of cooperation already mentioned with its substantial usefulness.

This aid provided daily, most of it really nothing more than fire-fighting and overcoming sudden difficulties resulting from a lack of organization, inevitably revives the suspicions following the formation of associations: What is this newer organization for? Why is there an association for the work which should proceed by itself according to the normal order?

While there is close cooperation between enterprises, the joint work of experts working in individual plants does not yet in general belong to the daily order of things, although this is the only way that the "Let's Do It Together!" movement can replace the "Do It Yourself!" slogan, and is one of the indispensable conditions for an increase in productivity. The productive associations can serve as an example of this.

FARMS ATTEMPT TO OFFSET HIGHER COST OF INPUTS

Budapest FIGYELO in Hungarian 20 Aug 80 p 11

[Article by Dr Laszlo Nemeti: "Cost and Revenue Ratios in Agriculture"]

[Text] The production increase attained in agriculture is realized from year to year at a greater material expenditure and a greater investment of fixed assets. The cost of materials used in agriculture between 1968 and 1978 rose about three-fold, while the gross stock of assets doubled. The ratio of material cost in 1968 was 68 percent of gross production value, and in 1978 it was 65 percent. But the material cost ratio of agriculture on state farms reached 80 percent by the end of the period under study, and on cooperatives it also approached 70 percent.

The ratio of net production values, including wages and individual incomes as well as net income, declined from 48 to 35 percent. But in the agricultural activity of state farms, this ratio was only 21 percent, and in the common production of cooperatives, 31 percent.

Why the Decline?

In the ratio decline of net production value a role is played, of course, by the rapid erosion of the number of agricultural workers and the lower net income content in agricultural producer prices. The wage income content of agricultural producer prices is about one-third of the national economic average. Thus the increasing use of industrial materials, because of the varying revenue content, further limits the revenues of agricultural production.

The change in the cost and revenue ratios is also indicated by the fact that the net income content of the agricultural operations' gross production value is gradually declining. While in 1968 the net income content in 100 forints' worth of gross production value came to 10.7 forints--an outstandingly high 15.2 forints in 1969--it did not come to even 10 forints in the excellent production year of 1977. In 1978, it declined to 8.9 forints. The revenue decline is even more significant if we compare it to material costs. Net income per 100 forints of material cost

fell in the 10-year period under study from 20.4 to 13.7 forints. Thus, with the change in the cost structure, the profitability of agricultural operations gradually worsened.

In 1968, agriculture used about 2 billion forints' worth of driving and heating fuel. In 10 years this has doubled, and meanwhile prices also rose twofold. Thus the agricultural operations had to spend about four times as much, about 8 billion forints, to acquire these products. Fertilizer costs tripled, while the cost of herbicides rose nearly sixfold.

Fodder has a 44 percent share in agricultural material consumption. The volume of consumed fodder increased 43 percent in 10 years, but in the meantime foddering costs increased almost twofold.

Table 1. Gross and Net Production Value and Material Costs of Agriculture in 1978 (1968 = 100)

	Gross Production Value	Crop Production	Livestock Breeding	Material Costs	Net Production Value
State farms	200	180	223	228	137
Privately owned agricultural producer cooperatives, joint	197	187	217	236	144
Other farms	188	163	208	233	158
Total	194	179	214	233	150

In all three agricultural sectors, the development of the material- and means-intensive livestock breeding branches was faster than in other sectors of agriculture. The more rapid increase of material costs than of gross production value was also expressed by the slow change in net production value, which is shown in the following graph. [see next page]

In the foreseeable future we can count on a further price increase in material costs and particularly in industrial materials. This is also indicated by the fact that as a consequence of the 1980 price changes, as compared to the 11 percent rise in producer prices for agricultural products, the price of fertilizer rose by 16.6 percent, herbicides by 21 percent, parts by 24 percent, energy by 36.5 percent, and irrigation water by 500 percent. Thus in the future the efficiency of agricultural production will be most strongly influenced by the price of industrial materials, their quality and their rational and economic utilization.

Key:

(1) material cost
(2) gross production cost
(3) net production value

But the cost and revenue relations of agriculture are influenced not only by the individual sectors, but also by the varying cost and revenue ratios of the branches as well.

In the period under study the yield of wheat and corn has increased significantly, and thus the increasing production costs have been largely countered by the rise in yields, and there was a lesser need for price increases. At the same time in the case of sunflower and sugarbeet, given the slight rise in yield, the provisions for a return of the increasing material costs and the profitability of the producer incentive had to be assured primarily through price increases. As is evident from the data in Table 2, the profitability of wheat and sunflower has declined significantly while that of corn and sugarbeet has increased. With this, however, only the earlier imbalances were evened out, and in 1978 the revenue per 100 forints of cost was approximately equal in the 4 branches.

Table 2. Profitability of Certain Arable Land Crops in 1978 (1968 = 100)

	Wheat	Corn	Sunflower	Sugarbeet
Yield	165.4	168.9	116.1	103.2
Production value	162.5	185.9	176.3	178.4
Production cost	217.1	178.1	222.8	148.8
Revenue per 100 forints of cost	46.9	125.0	51.9	257.1

Material cost has increased in a noteworthy way. At the same time, as a result of large-scale technical development and industrial material consumption, live work utilization declined within 10 years by 93 percent in the case of corn, and 73 percent in the case of sunflower and sugarbeet.

Agricultural production which is based on modern technology depends more and more on industrial production. With the present price policy--when an increasingly greater share of industrial materials and means become free price products--the rapid price increase of materials of industrial origin may cause difficulties in agriculture, since 85 percent of the products that belong here, precisely because of the price stability of the basic consumer items, fall under the category of maximum or fixed price commodities. Thus we are unable to pass on the greater share of the price increase in agricultural operations and industrial materials and means.

The Production Structure

One of the most important problems of our economic policy is the development of an economic production structure. In view of the fact that in agriculture the cost and revenue relation of grain and several well-mechanized crop production branches are still more favorable than average, it may be expected that their production will be able to be stabilized in the coming years. This is also justified by the more favorable world marketing possibilities and the economy of these products. With the rapid production cost increase and the significant narrowing of machine price supports, the 1980 price measures may hinder technology replacement in the most machine-intensive branches of corn and sugarbeet production. Therefore, improvement in the profitability relations of these crops remains a central task.

We must analyze in greater detail the problem of the development of the livestock breeding branches since the increasing industrial means and material prices are strongly influencing their profitability. The increase in the crop production costs through fodders will also burden livestock breeding. Since the price of the products is defined primarily by costs, the rapid rate of increase in industrial means and material prices will in this way continue to lead to a rise in the purchasing prices of agricultural products.

The stability of prices of food, which form the most important part of total consumption, is also a function of the development of agricultural production costs. Therefore, the domestic industry can be of service through the manufacture of inexpensive and good quality resources and materials, while agriculture can be of service with their utilization in an economic way.

ENTERPRISE STRUGGLES TO PREPARE NEW FIVE-YEAR PLAN

Budapest NEPSZABADSAG in Hungarian 3 Sep 80

[Article by Dr Jaros Polonkai: "Enterprise Is Preparing a Five-Year Plan, Experiences of the Ganz Electrical Works"]

[Text] In the third quarter of 1980, planning operations to set the enterprise management goals at the Ganz Electrical Works for the Sixth Five-Year Plan will be completed. The change in the economic environment, principally the worsening of the terms of trade and the intensifying international competition, have modified the requirements for medium-term planning, and it demands of us a new outlook and methods.

If I were to compare planning work to target practice, the change of circumstances is characterized by the fact that while in the previous five-year plans we had to aim at a slowly moving target, we must now fire at objectives that pop up unexpectedly. (We must become accustomed to the fact, for example, that export-import prices and foreign exchange rates as well change frequently, and sometimes significantly, and more and more these factors influence the domestic profitability of these products.) Now in our plans we need to work minimally with firm figures, and seek rather to define clearly the range in which we can flexibly adjust to changes.

The Upper and Lower Limits of Demand

Greater flexibility is also made necessary by the fact that in 1979 a total of 22 percent of the production at the Ganz Electrical Works went for export on capitalist markets, 10 percent for socialist export, and 68 percent for meeting domestic requirements. Several years ago our total export hardly came to 10 percent, that is, the enterprise produced mainly for the domestic market. Under the Fifth Five-Year Plan the development was dynamic; the annual rate of production growth was between 10 and 15 percent, and between 1977-1980 it realized an investment of 750 million forints.

In the initial phase of planning a year ago, we came up with preliminary development ideas which were useful in that we had to examine the technical-economic situation and marketability of our product groups and search for the possible main lines of development. In the following phase of our planning work the emphasis was on establishing market requirements.

The survey of domestic market requirements is now substantially more difficult than before because most of the purchasers from the Ganz Electrical Works do not know how much money they will have in the next 5 years, although in this case we are speaking of investment products with a long completion time, energetics equipment, electric railway equipment, etc. Therefore, in indicating domestic requirements in advance, we have used methods different from the usual. First of all, we researched those products for which our biggest buyers, that is the electric energy industry and MAV [Hungarian State Railways], will definitely have a need. (Without replacing equipment that must be discarded without further delay, the economy's circulation would be stopped, its supply of electricity and railroad transportation would cease). We can regard this as the lower limit of demand. The upper limit in our plan is that sum which our customers are for the time being planning to invest if they have enough money for the investment.

The difference between the lower and upper limit accounted for in the planning of the enterprise varies by product groups. For example, while the variation in products required by MAV was within 10 percent, it reaches 30 to 40 percent in some kinds of energetics products. In the course of planning we sought, and are still seeking, gradually to reduce this difference with the acquisition of new information. We believe that in the survey of domestic demand we can within 5 years tolerate a difference of 10 percent, but not more. In demand we also measure, of course, whether we can meet import competition in price.

While domestic demand can be estimated relatively exactly and the buyers' intent is quite recognizable, it is not possible, because of its dimensions and unpredictability, to measure the capitalist market with such methods. To be sure, we have called on experts to make market surveys for us, and we have acquired foreign trade enterprise information, but we did not regard all these things as reliable enough for us to base our planning on them. In the course of specific analyses we came as a matter of fact to the conclusion that our export possibilities are limited not directly by the magnitude of the market demand, but decisively by the competitiveness of the enterprise. According to our calculations, it is on one hand through primary cost reduction based on technical development, and on the other hand through broader primary contractor activity that we can improve the competitiveness of the enterprise to the extent that it will make it possible to increase the exports of the Ganz Electrical Works by about 10 to 15 percent. The market will not set up barriers to such an increase, but we must count on annual fluctuations in export possibilities.

Domestic marketing and the minimal volume of planned capitalist export will together make it possible to exploit adequately the fixed assets of the enterprise, and the free capacity above the basic load we will seek to use to meet favorable cyclical market demands that cannot be foreseen.

Trends in Price Changes

Some problems are encountered by planners attempting to realistically establish market demands, but most planning headaches are caused by the numerical planning

of complex economic indexes like profit or means efficiency, for example. From prices through foreign exchange rates to economic regulators we must here take into account many such factors that are very difficult to plan. Therefore, we decided to leave out of the plan estimates all such factors where future development cannot be deduced from basic technical-development, and economic political trends. Thus we do not plan for changes in exchange rates and we do not count on such changes in regulators as directly modify profits. The above two factors we can regard as only "surface" phenomena which as effects reflect the changes of deeper economic interconnections. A foreign exchange rate change can be ignored because the unfavorable effect it may have on profit can be reduced to the minimum with rate of exchange insurance.

Regarding price changes, we count on two lasting trends in our plan. One of our assumptions is that energy prices, and the prices for energy-intensive materials (for example, chemical goods) will be relatively more expensive in the Sixth Five-Year Plan period as compared to other materials. The other trend that promises to be permanent is that the price index for finished products, with reference to the same technical parameters, will rise less than the index for materials and energy sources. This latter trend means, for example, that if a product line is produced with the same technology and the same cost expenditure as several years before, then the increase in material prices will not be recovered in the sale price, or profits will decline. This can be guarded against by the producing enterprises only by changing the product line and the production technology (and the related plant and work organization) as well as by modernization. The Sixth Five-Year Plan of the Ganz Electrical Works was also prepared in this manner, and we are counting by product groups on a specific material reduction of 10 to 15 percent.

The enterprise plan has two variants. In one variant, starting from a lower market demand, the annual rate of growth is 4 to 5 percent. In the other variant, assuming a brisker market demand, the average annual rate of growth is 7 to 8 percent. We regard the two variants as the lower or upper limit of our possibility for mobility. Our main task is to assure, even in the planning, such a flexibility in enterprise undertaking as will make it possible to move from one variant to another in accordance with the market change. We must also count on the fact that there may be further fluctuations both on the domestic and export markets.

Of course, two investment and technical development variants also belong to the above-mentioned two marketing variants, but these are closely related to each other. By this we mean, for example, that the larger investment variant can be developed from the smaller by making further additions (machinery and equipment) as, for example, with variable modern furniture where a three-part bureau series can be expanded with a fourth element if the needs of the family grow. In both cases, the planned investment is intensive, that is, we do not plan to create new production areas through construction; whereas machine investments, substantially machine replacements, we can adjust to the actual rate of growth by the above-mentioned method. By installing high-performance machinery we can reduce the number of work places as well.

Establishing the manpower demand was a hard nut to crack in the planning work. After a many-sided study, we are planning on a 2.5 to 3 percent annual reduction in our Budapest factory, and in our provincial factories we are counting on maintaining our present average number. On the enterprise level the annual reduction comes to about 2 to 2.5 percent. The sources of productivity are: technical development (for example, investments installed in the Fifth Five-Year Plan), changes in the product structure, and work organization and wage measures.

Organizational Measures

The plan will remain a dead letter unless we buttress it with organizational steps. Our enterprise is planning, for example, the following, more important measures:

--shortening of the chain of command within the enterprise, that is the development of a guidance oragnization that adjusts better to the work process, is less fragmented, and is more suitable to the profit incentive;

--putting internal information on continuous computers in the course of automatic accounting development, above all in the field of material management and production perparation;

--institutional expansion of work methods that promote management, including value analysis;

--realization of a smoother, internal manpower regrouping (from one work shop to another, or from one trade to another, a so-called related trade).

In the coming weeks we shall open the Sixth Five-Year Plan of the Ganz Electrical Works to debate in the democratic forums of the enterprise. The social control of our plans will make it possible to filter out any faults and to have the active collaboration of the workers in developing and realizing the common goals included in the plan.

TEXT OF 1949 TRADE UNION LAW PUBLISHED

Warsaw DZIENNIK USTAW in Polish No 41, 15 Jul 49, Item 293 pp 853-854

[Law dated 1 July 1949 on trade unions]

[Text] Part I. General Regulations

Article 1. For the purpose of the statutory securing of the most favorable conditions by the people's authority in Poland for the development of the trade unions with the intention of consolidating the victory and achievements of the working class, strengthening people's authority and the construction of socialism in Poland and also for the purpose of creating the most suitable conditions for further activity being developed by the trade unions in the field of representation and defense of the interests of the workers and white-collar employees, concern for the systematic and continuous improvement of the material and cultural situation in the world of labor, mobilization of the working class to carry out the production plans, increasing work productivity and developing competition, and permanently raising the national economy to a higher level:

1) the workers and white-collar employees are guaranteed the right to voluntarily organize in trade unions as well as to most actively participate in administering people's authority,

2) all regulations remaining as a legacy after the capitalist governments, which limited the right of the workers and white-collar employees to voluntarily group themselves in trade unions, which subjected the activity of the trade unions to the supervision of administrative authorities and also contributed to the breaking up of the trade union movement, are abolished.

Article 2. Workers and white-collar employees who are employed in enterprises, offices, and institutions, as well as other persons who are working on the basis of a work agreement, an apprenticeship agreement, or public authority appointment, have the right to voluntarily organize in trade unions.

Part II. Tasks, Goals and Scope of Activity of the Trade Unions

Article 3. The statute of the Association of Trade Unions (Zrzeszenie Zwiazkow Zawodowych) in Poland as well as the statutes of the trade unions which are entering into the composition of the association, describe in detail the tasks, goals and scope of activity of the trade unions. The Congress of the Trade Unions in Poland votes on the statute of the Association of Trade Unions.

Part III. Rights of the Trade Unions

Article 4. Paragraph 1. The trade unions through their statutorily-specified managerial echelons and union organs cooperate with the authorities and institutions in the field of public administration, the national economy, and supervision within the scope and manner prescribed by legal regulations.

Paragraph 2. In the area of the implementation of their statutory tasks, the trade unions represent those who are organized as well as those who are not organized in all matters which pertain to the general interests of the workers.

Part IV. Organization and Authorities of the Trade Unions

Article 5. Paragraph 1. The principal representation of the trade union movement in Poland is the Association of Trade Unions.

Paragraph 2. The Association of Trade Unions in Poland is a legal entity.

Article 6. The highest organs of the Association of the Trade Unions in Poland are:

1) The Congress of Trade Unions

2) The Central Council of Trade Unions.

Article 7. The procedure and manner of electing delegates to the Congress, their number as well as the dates for convening the Congress of the Trade Unions is described in the statute of the Association of Trade Unions in Poland.

Article 8. The Central Council of Trade Unions is answerable for its activity only to the Congress of the Trade Unions.

Article 9. Paragraph 1. The Central Council of Trade Unions maintains a register of the trade unions.

Paragraph 2. Each trade union becomes a legal entity at the moment of registration.

Part V. Interim and Final Regulations

Article 10. The rights of the Association of Workers' Trade Unions in Poland and the Central Commission of the Trade Unions, ensuing from the legal regulations in force, pass respectively to the Association of Trade Unions in Poland and the Central Council of Trade Unions.

Article 11. Rescinded are:

1) The decree dated 8 February 1919 on the subject of provisional regulations--on workers' trade unions (Dz. U. R. P. [Legal Gazette of the Republic of Poland] No 15, Item 209);

2) Article 7 and Article 11, paragraph 2, of the Decree of the President of the Republic, dated 27 October 1932 on the Law on Associations (Dz. U. R. P. No 94, Item 808), and in Article 9, point c), of that decree, the words: "with the exception of the provisions contained in Article 11, paragraph 2, and Articles 15, 17 and 19" are deleted.

Article 12. The Chairman of the Council of Ministers and the Minister of Labor and Social Affairs are charged with carrying out of this law.

Article 13. This law becomes effective on the date of promulgation.

President of the Republic: B. Bierut,
Chairman of the Council of Ministers: J. Cyrankiewicz,
Minister of Labor and Social Affairs: K. Rusinek.

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

DODE STRESSES NEED TO IMPROVE PLANNING ACTIVITY

Tirana ZERI I POPULLIT in Albanian 10 Jul 80 p 3

[Article by Petro Dode, chairman of the State Planning Commission: "The Perfecting of Planning and Its Methodology--Continuing Objective of a Profound Scientific Work"]

[Text] The level attained in the economic and social development of the country, the special historic conditions under which our country builds socialism, surrounded by imperialist and revisionist enemies, as well as the great tasks of the coming 5-year plan which is being discussed and drafted by the working masses of the city and the village under the party leadership, require that now and in the future, the research-scientific, creative and transforming activity, be raised to a higher quantitative and qualitative level, so as to transform science and technological progress into still more powerful social factors, which should contribute further and with greater effectiveness in the maintenance of high rates of economic development and the comprehensive strengthening of our socialist homeland.

The great tasks presented by the Eighth Plenum of the Party Central Committee require the further concentration of attention, care and work of the state and economic organs in the field of the development of the social and economic sciences and, in this framework, of the perfection of planning, so as to further raise its role in the entire process of socialist construction of the country on the basis of the party guidelines and directives. Planning and its methodology as a science of socialist economic organization and management in our country, have been and are the object of a continuous study to perfect their various aspects in accordance with the economic and social development of the country. The broad scientific work carried out in this direction, on the basis of the tasks set by the Seventh Party Congress, has influenced the further perfecting of the system of planning and the strengthening of its scientific character, by better solving and implementing, in the practice of the planned management of the economy, the problems of expanded socialist reproduction, in accordance with the demands of the objective economic laws of socialism.

The basis of the studies carried out for the perfecting of planning and of methodology has been the generalizations applied by the party and Comrade Enver to the revolutionary experience of the economic and social development of our country, as the only country in the world which builds socialism and develops the economy on the basis of a single and general state plan. The drawing up of the 1979 and 1980 plans and the achievements in the field of their fulfillments, through total self-reliance, as well as the work which is presently being carried out in drawing up the Seventh Five-Year Plan, are living proof of the important steps made during recent years in perfecting planning.

In our country where socialist relations have been established throughout in the city and in the village, no economic-social activity whatever can be understood or carried outside the plan and planning. However, the science of planning and methodology itself is made up of principles, criteria, methods, methodics and rules which must be rigorously implemented in every link. This is being stressed because often it is proven that various state and economic organs, as well as their apparatuses, are not, everywhere and in all issues familiar with, the requirements of planning methodology nor do they implement them properly. We must continue providing, especially, greater effort and help to the grassroots, because the scientific character of the plans at the center, their correct rates, dimensions and so forth, depend on the scientific level of planning in the enterprises and cooperatives. It is necessary for all the ministries and other central institutions to better deal with these tasks in order for the entire process of planning, from the moment of the drawing up of the draft plan at the base, the examination at various levels, the execution of the plan approved for the enterprises, cooperatives, and down to the smallest units of production and its implementation, to be carried out in accordance with the methodology of planning.

The dynamic and intensive development of the economy and the expansion of the economic dependencies and relations which originate from them, necessitate the constant perfecting of planning, thus turning the methodology and all other documents and norms which regulate planning into permanent study objects. This is necessary because life and practice confirm this and new problems are coming forth which require the perfecting of the planned management of the economy. Regarding this issue we must bear in mind the recommendations made by Comrade Enver at the Eighth Plenum of the Party Central Committee, that "Science and technology have progressed and developed in the direct service of the requirements of production and of social life, in the same manner that these in turn have been permanent stimulating factors also for the development of science and technology itself... The practice of society is a source of development of sciences and the criteria which confirms the justness of its theses."

The experience gained so far in implementing the methodology of planning presents problems in connection with the best possible implementation of

established principles and norms, as well as the need to further perfect some of the various aspects of our system of planning. In accordance with the implementation of the tasks assigned by the 7th Plenum of the Party Central Committee, and the speech of Comrade Enver at the meeting of the Politburo of the party Central Committee on 22 April of this year about economic-financial problems, as well as the recommendations and the tasks of the 8th Plenum of the Party Central Committee, currently a series of problems are being studied in cooperation with the districts, the ministries and the scientific institutions of the country, to further perfect the methodology and some other questions of relations in the field of distributions and compensation, related to the further strengthening of the planned management of the economy.

The perfection of the planned management of the economy today and in the future is related to the further deepening of the struggle against tendencies of globalism in the field of planning and to the fulfillment of the plan tasks which continue to be encountered in the practice of the organizational and management activity of the various state and economic organs, a practice which reduces to some extent the scientific level of planning. Therefore, during the study, special attention is being devoted to the seeking of the most suitable roads and forms which assure the perfection of planning in enterprises and cooperatives, in order to implement the established methodological criteria for planning in kind. The fullest possible solution of this fundamental issue of our socialist planning must be found by defining the ways and the measures to further perfect planning according to quality, productivity and cost per unit of production.

The aim of all these is that the plan define as correctly as possible the tasks of production in quantity, assortment and quality for the enterprises and the cooperatives, especially those which have a wide range of products and assortments so as to better fulfill the needs of the people, of the economy and of defense; by coordinating these also with the tasks of conserving as much as possible live and material work, not only in global terms, but, above all, also per unit of production and assortment.

Also, means of obtaining a fuller coordination of the indicators of the financial plan with the economic indicators where gaps are to be found today in the practice of planning work of the enterprises and cooperatives, and ways to better solve the problems related to the perfection of the norming of the means of circulation, of bank crediting and so forth must be studied more concretely. These issues require the best possible solution of the problems of methodology and of methodics which are related to the utilization of expenditure preventives and of crop accounts in the enterprises and cooperatives, so as to arrive at a better coordination and evaluation of the units of the economic plan with the indicators in value, especially of the expenses in the field of production and in other socioeconomic activities.

But planning in kind, and the entire scientific planning and management of the economy, cannot be put in practice successfully without further perfecting control over plan implementation in every link of the economy and without the fullest and most precise records of the entire economic-productive and financial activity of the enterprises and cooperatives. The improvements to be made in the system of statistical and accounting records in every link of production, must aim not only at enforcing quantity and assortment of production, but at the same time must have knowledge of the quality and quantity of the work time used for every product, the cost required to produce them, and to create the best possible conditions to deal with the problems arising in the field of their realization. The objective must be to strengthen the control and the pursuit of plan fulfillment everywhere, to confront the phenomena and to take measures at the right time, so that the plan tasks are realized properly in all indices.

On the basis of this must be improved the forms of accountability of the highest and lowest organs through systematic analyses and broader operational, statistical and accounting records, and for shorter time periods, of all the achievements in plan fulfillment, by taking into consideration here also the completion of thorough study analyses on the basis of the experience gained regarding the issues in connection with progress in expanded socialist reproduction.

The perfecting of planning requires not only the perfection of criteria, methods and so forth, which are related to the documentation and planning of tasks in the field of the development of productive forces, but also the perfection of socialist relations in production, especially in the field of distribution, exchanges and consumption of social product. The more correct use in the process of planning and plan fulfillment of the economic categories and levers, as well as the continuing perfection of the various aspects of expanded socialist reproduction which are an expression of relations in management in the field of distribution and of exchange of material goods, in accordance with the present level of development must guide the economic and social development of the country. The question here is to determine the best ways to use the wage system in the state sector and work compensation in agricultural cooperatives with greater effectiveness, in order to turn them into true incentives, into more powerful levers, in order to mobilize the workers in the fulfillment of the plan, but at the same time not permit the creating of great differences in income which would be of great consequences to our socialist economy.

Also, the studies which are being carried out must aim at solving the problems to be found in the field of contractual relations, of finance and of other relations between the enterprises and agricultural cooperatives, as well as between them and the bank, by also defining the measures to overcome the shortcomings which exist, and which in many cases become a hindrance to scientific planning and the fulfillment of the plan.

The tasks presented by the further perfection of the organization and management of the economy, and the further development and execution, in all the spheres of the country's life, of a broad and comprehensive research and scientific work, have also made it necessary to make improvements in the organizational structures of the various links of management in the economic and social sectors. Through the studies being carried out in this direction, we aim at achieving a more complete implementation of the recommendations issued by the party to further raise the effectiveness of management in all the links. This must be achieved entirely through a more rational use of the quotas approved in the existing structures, by improving the ratios between laborers and office workers, and not by resorting to exaggerated and unsound increases, as is the case in regard to tendencies evident in some state and economic organs.

Therefore, the improvement of organizational structures must be achieved through measures to strengthen the work organization of the state and economic organs and of their apparatuses, by assigning to each a full task, by improving the workers' skills, and by introducing machines in the work of accounting, statistical recordkeeping, of bookkeeping, and so forth.

The plan, in itself, is the result of a creative scientific work. Hence, all the state and economic organs must correctly understand and execute the measures which must be taken continually, so that the work in drawing up the plan, from the enterprise and up to the economic cadre, is preceded by studies carried out by all the branches of science and all the state and economic organs and their apparatuses.

Although the established methodological criteria make it necessary for the scientific studies to precede the plan, and in spite of the progress made, especially in recent times, in research and scientific work, the studies do not adequately respond to the tasks which the party has presented and presents in the development of the economy and culture for a number of issues and in some directions. This situation arises not so much because the possibilities do not exist, but because of the erroneous concept of some management organs and cadres that the planning process is more an administrative activity, by relying on some data which are not sufficiently the result of scientific, technical and technological studies and of thorough economic-financial studies and analyses. This is also the source of those manifestations which continue to be observed, in some places more and in some less, in the various links of production and of management, where the specialists and the cadres of various professions are not properly involved in continuing work and long-range studies, for the development of the sectors in which they work.

There are many possibilities in this direction if we keep in mind the fact that in production and in other sectors and in the management of the economy there are currently employed over 46,000 specialists and higher cadres, tens of thousands of other middle-level specialists and exemplary

workers and cooperative members who constitute a large human force for the advancement of production and technical-scientific revolution. Today we have, in addition to the Academy of Sciences and some institutes, many other scientific research institutions and units, technological bureaus and study groups attached to the enterprises and other links of management, as well as a substantial number of educational and scientific workers from Tirana University and other higher schools.

The better management of this great mass of workers of our Albanian science to carry out studies in the various fields of the development of productive forces, the perfection of socialist relations in production and in all the other spheres of endeavour of the country, must lead to the elevation of the level of knowledge, for a more scientific planning and management, to maintain higher rates and greater economic effectiveness in social production, and to solve, by relying on our own forces, the great problems which the full construction of the socialist society presents. Important tasks arise for us, for all state and economic organs and scientific research institutions to expand the completed studies related to the drawing up of the Seventh Five-Year Plan, so that the projected tasks will not only be documented, but also so that their realization will be guaranteed.

Regarding this issue, it is necessary for us state and economic organs to reflect as thoroughly as possible upon the recommendation made by Comrade Enver Hoxha at the Eighth Plenum of the Party Central Committee, that: "The tasks contained in the report on scientific research work, which was presented to the plenum... must be considered as an integral part of the 5-year plan which we are preparing. Science must help the planning of production, must lead production and must open prospects for the development of the economy and culture."

We must also do better work so that economic studies and problems of scientific planning will be the permanent object of the work of the economists, financiers, engineers, agronomists and other specialists, with concrete tasks and with a stronger requirement of accountability for their implementation and for the development of economic thought in the enterprises and cooperatives and in other economic and state organs.

The fulfillment of all the objectives presented by the Eighth Plenum of the Party Central Committee, confronts us with the following tasks: together with the scientific institutions, we must better study and define the roads and the measures which must be taken to perfect the methodology of drawing up the plan of the scientific research work itself, for documentation, with the technical material basis and with the workers needed for the execution of studies as well as with the content itself of the subject and the effectiveness of the problems which will be solved by their study and execution, to better guarantee the objectives which are set in the plan. By drawing our tasks from the materials of the Eighth

Plenum of the Party Central Committee and the pragmatic speech which Comrade Enver delivered to this plenum, the workers of the state and economic organs, and in this framework all the economists, will keep at the center of attention the perfecting of planning and of methodology, so as to always and better serve the raising of their role in the entire socioeconomic activity of the country, from the base and to the center, and for the proper fulfillment of the tasks defined by the state plan.

SHORTCOMINGS IN ACTIVITY OF SAVINGS BANKS CITED

Tirana BASHKIMI in Albanian 17 Jul 80 p 2

[Article by Fadil Kepi, director of the Institute of Savings Banks and Securities: "Savings Deposits--An Indicator of the Rise in the Well-Being of the Working Masses"]

[Text] As a result of the correct policy of the party, of the uninterrupted strengthening and development of the economy and the continued rise in the well-being of workers, savings deposits have also increased from year to year. All the districts of the country have achieved good results in increasing savings deposits. At the end of 1979, they increased 3.4 times in comparison with 1965, and over 2 times in comparison with 1970. Today, the network of savings banks has been expanded everywhere. Our entire country is served by 26 branches with 100 savings banks and about 3,400 accounting offices in work centers and in agricultural cooperatives.

The number of depositors and the average deposit amount per worker has grown steadily from year to year and in every district. In 1979, the number of new depositors increased by about 72,000, whereas the average amount of deposits has increased continually from year to year. Marked changes have taken place also in the structure of savings deposits. The majority of depositors are workers and cooperative peasants whose numbers have tended to increase from year to year. In 1960, the deposits of workers and of agricultural cooperative members amount to 42 percent, whereas in 1979 they were about 70 percent of all the deposits. In 1979, there was one savings account for less than 3 persons, in comparison to one savings account for about 7 people in 1960.

The savings banks, as important organs of our financial system throughout the country, are used by the people to deposit a part of the temporarily free monetary resources. The savings deposits which are temporarily free are used as supplementary resources to finance and further develop the economy and to accelerate monetary circulation. By taking into consideration the fact that our lek is one of the strongest currencies in the world, which knows no devaluation and inflation so common in the bourgeois-revisionist world, the income which the population earns through the 2-3 percent of interest paid for the money deposited, further contributes to

the increase of well-being. In order to further help the depositors, in addition to the expansion of the network of savings banks and savings offices in work centers, facilities have been set up for the depositors for speedy service. The savings book gives every depositor the right to withdraw his money from any savings bank of the Republic. Even in cases of loss of the savings book, the money of the depositor is nevertheless guaranteed and the deposited money is not endangered at all. The depositor is provided with a new savings book, and he continues to enjoy all the rights he had before.

We are aware that despite the achievements, much remains to be done by the workers in the savings banks and insurance area, both in increasing savings deposits and improving services to the people. We have concentrated our work on improving propaganda to popularize the importance of increasing savings deposits as a means of correctly combining the general interest with the individual interest. This requires that the workers of the savings banks further increase their cooperation with the mass organizations in work centers and in the city quarters, so as to turn the practice of savings in every family into an inseparable part of their daily life. Experience has shown that the best propaganda is the continual improvement in serving the people, for the depositors to be served more quickly, better and in a polite manner, and for the bank workers to waste as little time as possible in carrying out their functions. This problem has been of considerable concern to us, because as is known, today the savings banks perform other activities too, such as issuing paychecks to retirees, collecting bills for communal services which are constantly increasing. Lately, as a result of the closer cooperation with some retirees, financial organs and mass organizations, there has been improvement in paying the checks to retirees by setting up a proportionate distribution system for the savings banks on established days. This form of work has made it possible to expedite payments to the people. But there are greater possibilities for improving the level of our work and continually perfecting it on the basis of the experience gained. All workers of the savings banks and insurance field must therefore try harder to perfect our method of work and management. Despite the improvement in our work, there are still shortcomings and weaknesses, above all as regards the strengthening of internal work, of the precise execution of financial discipline, of the laws and rules established for this purpose. These have been more evident in Puke District, Kruje District and others. From the investigations carried out this year in some branches of savings banks, we have concluded that it is possible to avoid these shortcomings, that they are subjective, and that they are a result of the poor knowledge of the rules which determine the process of activities, and in some cases are also the result of liberal attitudes of some workers. The workers of the savings banks and insurance field, and all the workers of the financial system, must be characterized by correctness and accuracy in their work and all activities.

An important role is also played by the financial investigation and auditing branch. No savings bank or agency can fail to be audited within the established deadlines. The plan of unscheduled auditing and investigation is being practiced and carried out quantitatively and qualitatively, further elevating the role of preventing shortcomings and weaknesses. Last year, Shkoder District, Vlore District and Elbasan District did not fulfill the investigation auditing plan. In the same way, the investigation auditing plan of the savings agencies was also not fulfilled in some districts; this should have been carried out by the auditors of some work centers. Shortcomings have also occurred in work in Fier District, Lushnje District and others. The directorates of these branches, in cooperation with the investigation and auditing sections of the districts, must fight harder so that the investigation of the savings agencies will be carried out within the established deadlines and with good quality, and they must combat the mistaken notion of some auditor of the enterprise or agricultural cooperative that it is not up to him to exercise control. These activities harm the work and open the door to evil-doers.

The closer cooperation with the financial directorates and central ministries, the investigation and auditing and finance sections and the state and agricultural bank, has made it possible for the problems of the increase of savings deposits not to remain problems of the workers of savings banks, but has enabled these organs to monitor them by correctly evaluating them and by considering them as their duties. We are devoting greater attention to the close cooperation with some of the agricultural cooperatives and the peoples councils of the unified villages, where the number of potential depositors is still low. The objective is for all the peoples councils of unified villages to open savings agencies. A good work is being done in this connection in Korce, Erseke, Vlore and Mat districts. In order to implement these duties, we are paying attention to the further improvement of workers' skills through correspondence schools, seminars, and other forms of education, so they can familiarize themselves with and accurately implement our socialist legality.

CONSTRUCTION INDUSTRY PRESENT, FUTURE EVALUATED

Prague PLANOVANE HOSPODARSTVI in Czech Nos 5, 6, 1980

[Article by Eng Vladislav Kmoch, State Planning Commission: "The Construction Industry in 1980"; passages enclosed in slantlines are in boldface in original]

[No 5, 1980, pp 30-41]

[Text] Currently, political and economic initiative is aimed at fulfillment of the tasks assigned by the 14th KSC Central Committee session and the plan for 1980, and at preparing the draft plan for 1981 and the foundations for the draft Seventh Five-Year Plan.

It was stressed at the 14th KSC Central Committee session that construction industry workers are required to carry out consistently the tasks laid out for them by the Sixth KSC Central Committee session. These involve primarily the activization of potential construction capacities throughout the construction industry and in all spheres of comprehensive socialist rationalization. The necessary conditions for this must be assured both by the investors in and purchasers of construction capacities, of whom timely planning and site preparation are required, and by the other sectors of the national economy which create the material and technical base for construction.

The performance of the 1980 plan concludes the Sixth Five-Year Plan and is the initial basis of the Seventh Five-Year Plan, which makes it necessary that the development of the construction industry be oriented towards the economic conditions of the latter and that a smooth transition from one five-year plan to the next be assured. Implementation of the 1980 plan too must be directed with a knowledge of the basic directions of development of the construction industry in the Seventh Five-Year Plan, in particular as regards adapting the structure of the construction sector to the requirements of capital construction, concentrating manpower and production facilities on the key substantive tasks and geographical priorities, and, in technical development, constantly seeing to it that the consumption of

fuel, energy and metal is decreased and using the reserves of manpower and capital assets more effectively by increasing management and organizational quality.

/It is a basic task of the construction industry to adapt and develop the structure of its capacities in keeping with the requirements of capital construction, reconstruction and repair of capital assets, buildings and structures. This means filling out the production enterprises' production programs with construction projects in keeping with the aims of the state plan and carrying them out in time periods which are in accord with the requirements of the national economy. The Czech and Slovak construction ministries are of key importance in the performance of capital construction. In addition, the state plan imposes on the other central organizations which manage contracting construction organizations the requirement of using construction capacities in keeping with the requirements of the national economy. Thus the structural development of the construction industry has a sectoral character (even when limited to the contractor construction organizations), and its efficiency and flexibility require that specialization and cooperation between construction enterprises within the sector be deepened./

In terms of its organizational structure and the associated division of labor, the construction sector includes construction organizations managed by federal agencies (the Federal Ministry of Fuels and Power, the Federal Ministry of Transport, the Federal Ministry of Metallurgy and Heavy Engineering and the Federal Ministry of National Defense), by the Czech and Slovak construction ministries and by the national committees (District Construction Enterprises and Silnice National Enterprise), and the ministries of agriculture and food. The breakdown of their work in capital construction during the Fifth and Sixth Five-Year Plans and in the plan for 1980 shows the following developmental trends:

	Index: 1980 plan / 1979	Average annual pace: 6th Five-Year Plan	Average annual pace: 7th Five-Year Plan	Percentage of total amount of work: 1980	1975	1970
Capital construction overall	104.2	5.0	7.4	100.0	100.0	100.0
Organizations managed by:						
Federal agencies	98.3	0.3	8.4	9.3	11.7	11.2
Czech and Slovak construction ministries	105.2	5.8	7.9	77.3	74.5	72.9
Czech and Slovak national committees	101.5	5.2	3.3	9.8	9.7	11.8

The share of the construction organizations managed by the Czech and Slovak construction ministries has increased slightly, which is in accordance with the directing of their construction capacities toward key investment programs of the national economy. It appears that the share which they have attained is near the upper limit of efficient division of labor in the sector and that more capacities for the new investment programs must be created by regulating the content of the construction enterprises' production programs for 1980 and by completion of construction projects.

Concentrating the construction capacities of the construction ministries on national economic priorities requires both faster completion of construction projects and the use of the advantages of division of labor in the construction sector. This means in particular that enterprises in the construction ministries are to carry on construction projects amounting to less than 2 million korunas RN [budgetary expenditures] only when they have a technological relationship to projects which have been designated priority tasks of the state plan and are associated with capital construction in areas of concentrated capital construction. Carrying this conception through requires rather consistent coordination of production programs, primarily in the departments which are carrying on capital construction either with their own construction capacities or with those of the construction ministries.

/The sectoral load on construction capacities is specified by the state plan. An important role in preparation for the Seventh Five-Year Plan is played by guiding their utilization in terms of cooperation in the performance of capital construction in the national economy, particularly between construction organizations managed by the ministries of construction and construction organizations managed by the central federal agencies in the performance of their own capital construction. The case is similar for construction organizations managed by the national committees and construction enterprises of the ministries of construction and other departments./

/More thorough specialization and cooperation, not only within the individual departments, but in the supplier and subsupplier system for performance of capital construction, is one way of speeding up the capital construction process and making it more efficient, bringing about a more flexible structural transformation and making more uniform use of construction capacities within the sector.

The state plan specifies the breakdown of utilization of construction capacities for capital construction, export and repair of capital assets, buildings and structures. Maintenance of the main balances between capital construction and utilization of the construction capacities in the state plan for the individual central organs, the middle management levels and the direct investors and suppliers is an extremely complex process which demands maintenance of national economic proportions.

One negative influence of supplier-purchaser relations is the urging by some to carry out construction projects which deviate from the established concept of capital construction of the individual sectors and branches. In this situation, requests in excess of allocated investment resources are primarily explained as a lack of balance in the state plan. The essence of these divergent approaches, however, is the pressing of requests in excess of the planned construction capacities, frequently at the cost of increasing the amount of unfinished construction and lengthening construction time. Another factor in these deformations of the intent of the state plan is the enterprise interests of the suppliers, for it is beneficial to start construction projects given the current breakdown of the machinery inventory and of worker skills. A further factor is hitches in the supplying of construcion projects and performance of specialized work, which slow down progress on uncompleted projects and provide room for increasing the number of starts. In sum we may state that enterprise interests are asserted in conflict with the established proportions of the state plan and the balanced supplies of construction capacity.

These questions gain in importance in preparing for the Seventh Five-Year Plan; discipline and adherence to prescribed limits is one of the most important preconditions for improving the quality of the planning process and management of capital construction. Criteria similar to those for poor-quality products should be used for poor-quality foundations for the national economic plans involving nonadherence to the basic parameters and limits.

In this connection it is useful to recall the decree of the CPSU Central Committee and the USSR Council of Ministers on improving planning and increasing the influence of the economic mechanism on increasing production efficiency and labor quality, which stated that the five-year and annual plans of the production enterprises must be developed on the basis of economic and engineering calculations, i.e. within the framework of the input and output data specified by the plan.

The use of construction capacities in the state plan is guided by the system of balances, priorities and priority tasks, which are specified in a directive manner and form the axis of supplier-purchaser negotiations. A knowledge and understanding of these, in connection with economic policy, is a basic precondition for improving the efficiency of planning work and deepening substantive performance of the state plan.

/The state plan guides the utilization of construction capacities in accordance with the structure and territorial distribution of capital construction. The guideline balance of construction work for capital construction specifies in the plans, and also in the 1980 plan, the amount of work that can be done for the individual central investors by the contractors' central offices. This in essence limits the amount of capacity for specific central investors, while their specification along

the vertical management axis, together with supplier-purchaser negotiations, fulfills the investment program of the state plan./

The state plan for 1980 has been drawn up in accordance with expected plan fulfillment for the preceding year, and it was necessary to allow for possible slippages on individual projects. Accordingly, the 1980 plan allocates some construction capacity for making up shortfalls in projects worth more than Kcs 2 million RN. Thus the state plan creates some leeway in capacities for making up unfulfilled tasks of the previous year and accordingly for holding steady or possibly decreasing the amount of unfinished construction. Thus it is a case of making the performance of capital construction more realistic, and in monitoring plan fulfillment for 1980 it must be consistently required that these reserve capacities be treated in accounting as specified by the state plan.

The large amount of uncompleted construction and the consistently low mobility and adaptability of construction capacity to the requirements of capital construction, together with the limiting supplies of certain materials and products, require that within the overall amount of work, priorities be set in the performance of planned tasks; these are also basic criteria for evaluating plan fulfillment. Long-standing failure to fulfill the capital construction plan in projects worth more than Kcs 2 million RN decreases their national economic effectiveness and requires their priority performance by the construction organizations and the investor departments.

The 1980 state plan establishes the priority task of providing construction work for projects worth more than Kcs 2 million which are subject to regulation of the amount of incomplete construction by means of a limit on budgeted expenditures for construction starts. The total quantity of such work to be provided varies for the different central suppliers and construction enterprises. For Czechoslovakia's construction organizations as a whole, the share allocated for regulated projects worth more than Kcs 2 million RN is 46 percent of the total, with a figure of 44 percent for construction organizations managed by federal agencies, 49 percent for those managed by the Czech and Slovak construction ministries and 24 percent for those managed by national committees. The priority of plan fulfillment in these projects is also expressed through regulation of wages payable. When the planned output quantities are exceeded, the economic organizations may revise planned expenditures only to the extent that they exceed or at least fulfill the delivery figures.

The state plan priority for products worth more than Kcs 2 million RN will continue in force; but in the directives for the 1981 plan it is specified in detail for the totality of projects worth more than Kcs 2 million, other than comprehensive dwelling construction, which has independent conditions. The plan directive gives the construction enterprises basic guidance in the utilization of construction capacities.

Thus, in carrying out this year's plan and preparing for 1981 it is essential to create the technical and organizations conditions for concentrating capacities on these projects.

The increased specificity of the tasks and the heightened directive nature of the employment of construction work in the state plan increases the demands for input information and its analysis, and in this connection the request for stability of the five-year conceptions of the state plan is justified. The use of machine processing of the production programs of construction enterprises in the ministries of construction, and gradually throughout the construction sector (each project has its own card which specifies its characteristic technical, production and economic parameters), will make it possible to tie the national economic balances of construction capacities more closely to the construction system for all levels of planned management of construction work and for the other participants in investment process.

/This system will also be used in drawing up the Seventh Five-Year Plan and will be linked with tested and proven regulation of the structure of construction capacities specified by the guideline limits on the furnishing of construction work to the individual central investors, within which not only all uncompleted construction in the Sixth Five-Year Plan, but in addition all priority tasks, centralized construction projects and selected investment programs being prepared for commencement in the Seventh Five-Year Plan must be covered. The filling out of the performance program with other construction projects will be checked at the supplier and investor level and will be discussed by the central organs both in overall terms and separately for products worth more and less than Kcs 2 million RN within the framework of the above limits./

Past experience indicates that hard and fast delineation of the production program, with a full load on planned production capacities for the five-year plan, has a negative effect on carrying out the construction projects, because an allowance must be made for refining individual production project figures in the annual plans. In particular, full performance on priority projects requires a certain degree of freedom as regards capacities, which must be allowed for in drawing up the 1981 plan and the Seventh Five-Year Plan.

The extent of this freedom will differ with individual enterprises according to the nature of the construction. But the main requirement is that it make possible, in plan fulfillment, an adjustment to the priorities of the national economy, in keeping with designated construction schedules and the deadlines for putting capacities into operation.

The procedural instructions for developing the draft Seventh Five-Year Plan specify that construction enterprise production programs throughout the construction sector should be machine-processed into data structures that will make it possible to arrange basic cooperative relations and

division of labor within the construction sector. The use of these methods in preparing the Seventh Five-Year Plan depends throughout and fundamentally on disciplined, high-quality preparation of the base data, particularly in the organizations in which this system will be introduced. This system, which effects a linkage of the building performance plan with the capital construction plan, is an approach to modeling the comprehensive satisfaction of the requirements of capital construction by means of complete knowledge of the production program and a higher degree of management of the investment process throughout the sector.

Another priority category of the state plan for construction organizations is the quantity of work on construction projects designated priority tasks. Also included in this category starting in 1980 will be the amount of work on centrally reviewed construction projects designated for completion. The capacity committed to these projects out of the total quantity of capital construction work is as follows:

(%)	1976	1977	1978	1979	1980
Construction organizations managed by:					
federal organs	25.2	19.4	18.6	27.1	19.6
CSR and SSR ministries of construction	21.6	22.9	23.3	23.7	24.6

The proportions given characterize the breakdown of utilization of capacities according to state plan priorities; but in addition, the amounts of work in areas of concentrated capital construction are also included as priority tasks.

/The 14th KSC Central Committee session stressed that the construction organizations must more consistently concentrate their capacities on key investment programs. The plan for 1980 designated for the individual priority projects the quantity of work to be done, progress deadlines and the required deliveries of structural members. In addition, the operating conditions needed to assure these progress deadlines and project completion deadlines in accordance with the state plan are worked out for individual projects. Possible adjustments on the amount of work on state plans away from the state plan figures are possible only when the total amount of work required to be provided by the individual central supplier organs for the individual central investor organs is preserved./

In the state plan for 1980, 264 projects are designated as priority tasks; 37 of these are in the North Bohemian Kraj. In additionk the specifications of the amount of work on compulsory porjects includes amounts of work for 116 projects centrally reviewed as regards completion.

Fuel and energy base projects have priority in the performance of these projects.

In the past, even when they failed to fulfill their plans for capital construction work, the construction organizations fulfilled and overfulfilled their assignments for total quality of work on priority projects, but in individual projects this was not always done in a way commensurate with real progress. Accordingly, in evaluating fulfillment of this year's plan during the course of the year, the main stress must be placed on meeting deadlines for handing capacities over and putting them into operation and on completion of projects, including progress deadlines which are critical for handing over selected capacities and putting them into operation. This means valuing substantive fulfillment of the targets for construction progress over fulfillment in value terms. In keeping with the stress on the importance of priority projects, which are mostly critical for expanded socialist reproduction, completion schedules must also be maintained on the other projects, thus decreasing the amount of uncompleted construction.

In keeping with what is emphasized above, the according of priority to key projects cannot be combined with approaching the other capital construction projects as supplementary production, thus making it possible to make up shortcomings in the reproduction process and possibly also poor-quality management and organizational work. The current priority accorded to key projects is not an economic category, but the result of shortcomings in the performance of capital construction. The aim of the management process is to achieve uniform plan fulfillment in accordance with the deadlines laid down in economic agreements on all construction projects included in the production program. The path to this goal is faster concentration of currently dispersed capacities. Experience indicates that this task must be approached with specific measures in the production program of each production enterprise, for we cannot rely solely on the effects of the incentive system.

According to data from the Czech Ministry of Construction, the current structure of the construction enterprises' production programs for capital construction, given in terms of the number of projects in the Czech Socialist Republic, is as follows:

	Total construction	Priority projects	Priority worth over Kcs 2 million RN	Priority worth under Kcs 2 million RN
Overall				
number of projects	7,140	739	2,893	3,508
percent	100.0	10.4	40.5	49.9
Performed by organizations managed by:				
federal organs				
number of projects	1,141	114	512	515
percent	100.0	10.4	44.9	45.1
ministry of construction				
number of projects	3,145	524	1,772	849
percent	100.0	16.7	56.3	27.0
national committees				
number of projects	2,854	101	609	2,144
percent	100.0	3.5	21.4	75.1

The current situation, characterized by dispersion of capacities over a large number of projects, requires development of specific organizational and management measures, in cooperation with the other participants in the investment process and within the planned quantities of work. This will speed up work on projects which are important for the national economy because they conserve energy, improve export capabilities, represent anti-import measures, and the like, possibly at the cost of other projects which, according to these considerations, may be put into operation on slower schedules.

The utilization of construction work in the national economy is specified by the state plan over the organizational structure of the investors and according to the importance of the project (projects worth more than Kcs 2 million RN, priority projects). Also specified is the territorial distribution of construction capacities in accordance with the program for capital construction in the Czech socialist republic and the Slovak socialist republic, and also in the areas of concentrated capital construction, which include Prague, the North Bohemian KNV [Kraj National Committee] as priority tasks; their fulfillment is a criterion of fulfillment of the enterprises' planned tasks used in running evaluation of plan fulfillment, while the recomputation of planned wage expenditures for overfulfilling the planned quantity of production is linked to it.

The territorial specification of priorities is a result of the fact that the current distribution of construction capacities is not in accordance with the geographical requirements of capital construction, and that these disproportions must accordingly be made up by transfer of construction capacities.

The essential aspect of the transfer of construction capacities is relocation of workers to projects outside the area of their permanent residence. The existing distribution is the result of historical development and it has not been possible to overcome it in the time required through planned regulation or to relocate capacities in accordance with the requirements of capital construction. The basic task is that of building local construction capacities and creating mobile capacities which can equalize supply and demand, particularly as regards specialized trades and types of work within the oblasts and republics, or sometimes nationwide.

/The development of construction capacities and the meeting of needs for construction work in terms of geographic distribution is one of the most complex and demanding tasks of the construction industry, because their fulfillment entails transfers of workers, which are and will be an increasingly demanding problem because of the high standard of living and the strong demand for manpower. The construction industry has been generally successful in mastering these difficult tasks, and during the Fifth and Sixth Five-Year Plan the following concentration of construction capacities has been achieved in relation to requirements of capital construction:/

Location of construction work	Indices 1980/1979	Indices 1980/1975	Indices 1975/1970	Percentage of total amount of work 1980	1975	1970
CSR	103.6	121.2	150.0	100.0	100.0	100.0
in Prague	102.6	125.8	200.8	18.8	18.1	13.5
in North Bohemian KNV	103.1	124.3	173.1	15.7	15.3	13.2
SSR	104.2	130.7	154.6	100.0	100.0	100.0
in Bratislava	107.5	129.4	212.2	15.1	15.3	11.1

The table indicates the high degree of geographical concentration of construction capacity; a third of all construction work in the Czech Republic is done in Prague and the North Bohemian KNV.

The overall figures do not adequately express the demands of the task. For example, the Ministry of Construction carries out almost 40 percent of its building work in these areas.

Concentration of construction capacities and their transfer from kraj to kraj were particularly intensive during the Fifth Five-Year Plan; overall,

production increased by Kcs 9.5 billion in this period and by an additional Kcs 4.7 billion over this high level in the Sixth Five-Year Plan. During the Fifth Five-Year Plan, in order to assure increased output in these areas, an increase of about 40,000 workers was required, which made possible a broadly-conceived social program and particularly the construction of residences comparable to hotels. A material and production base was built at the same time, although it must be stated that this was not done intensively enough and for the most part fell behind construction requirements, and that the production bases still do not fully utilize the benefits of sectoral integration.

The construction industry is handling the planned quantity of construction work for the Sixth Five-Year Plan in areas of concentrated capital construction, although substantive plan fulfillment lags behind the capital construction program and is affecting the smoothness with which both public utilities and facilities and projects on which development of the fuel and energy base depends are made available. The carrying out of this year's plan and the preparation for 1981 require creation of the conditions for smooth construction and for the corresponding smooth utilization of workers and machinery. In these areas in particular, the Soviet construction industry sets an example in the mastery of demanding tasks with a high level of geographical concentration, whether it be residential construction in Moscow and other cities, or industrial construction in areas with reserves of raw materials, and it does so under incomparably more difficult natural conditions and with longer transport distances.

The connection and coordination of the capital construction plan with the construction work plan make the tasks in comprehensive residential construction (KBV), apartment construction and construction of the public utilities and facilities of residential towns more specific. The state plan explicitly sets the assignments for comprehensive residential construction and specifies the number of apartments required to be completed in order to accomplish the social program of building a developed socialist society. In the Fifth and Sixth Five-Year Plans, construction work on comprehensive residential construction developed as follows:

	Indices			Percentage of total work on capital construction		
	1980/1979	1980/1975	1975/1970	1980	1975	1970
CSSR overall	110.5	129.3	127.7	30.9	30.4	34.2
By CSR and SSR ministries of construction	109.9	127.9	130.3	91.4	92.4	90.6

In the breakdown of work by contractor organizations, about 30 percent of the total was on comprehensive residential construction, which is 90 percent carried out by construction organizations belonging to the Czech and Slovak ministries of construction. Comprehensive residential construction accounts for almost 40 percent of these organizations' total capital construction work and is a key factor in their fulfillment of both the production plan and the economic indicators.

There is a systematic failure to accomplish the planned amount of comprehensive residential construction, particularly public utilities and facilities of residential towns. For Czechsolovakia as a whole, the plan for 1979 was about 93 percent fulfilled. Thus Kcs 1.4 billion worth of work was not done. For the Sixth Five-Year Plan, nonfulfillment amounting to about Kcs 3.8 billion is expected. The planned pace for 1980, with a growth rate exceeding 10 percent, is a highly demanding task compared with the approximately 3 percent growth rate achieved in 1979 and requires, in relation to the tasks of the Seventh Five-Year Plan, the creation of the technical and economic conditions for continuing mastery of capital construction.

The causes of the current state of affairs are well known, and all participants in capital construction have a share in them, starting with territorial and planning unpreparedness and lagging development of the production base for new standardized systems, and extending to nonfulfillment of their duty by subsuppliers of construction work and suppliers of materials and products. These shortcomings are centered particularly in the regions of concentrated capital construction and represent the main problem in assuring plan fulfillment for 1980.

The construction tasks which are part of comprehensive residential construction are being fulfilled. The 1980 plan requires the contractors to complete 92,415 apartments, about 10,000 more than were made available in 1979; the 1979 increase over 1978 was not quite 2,000. This comparison indicates the demanding nature of this year's plan, whose fulfillment is essential for achieving the planned number of apartments for the Sixth Five-Year Plan.

The apartment construction assignment itself is being fulfilled, although with major hitches during the year in making them available. But this was preceded by the construction of a modern production base in the first half of the 1960's, when 18 panel plants with a capacity of about 20,000 apartments were put into operation. In addition we should note that the basic precondition for fulfilling the planned tasks regarding the economic parameters of the industrialized building industry is the development of a modern production base, and accordingly this is also a primary task in connection with the Seventh Five-Year Plan assignments for fulfillment of its own capital construction plan by the building industry's production base.

Apartment construction is being carried out by the contracting and cooperative construction organizations and by public self-help. During the Fifth Five-Year Plan, about 615,000 apartments were made available; 394,000 by the contractor organizations, 167,000 in single-family houses, and 54,000 by cooperative self-help. During the Sixth Five-Year Plan it is expected that the planned assignment will be exceeded and about 650,000 apartments will be made available; the increase will be primarily from the contractor organizations.

Apartment construction has developed into a highly industrialize branch of construction in which currently an average on-site labor consumption of about 520 hours per apartment has been attained, with conditions favorable for a further decrease. However, it is necessary to concentrate on decreasing overall labor intensiveness (including nonconstruction-site labor intensiveness), particularly in the prefabricated product plants and auxiliary operations, by minimizing investment intensiveness when economizing on labor.

However, the construction industry is faced with entirely new tasks resulting from the requirement of reconstructing existing apartments. In the next five-year plan we must expect that 40,000-50,000 apartments will be involved. Even though this year the problem does not directly affect production, it is nonetheless necessary to solve it, particularly in relation to the production base, for the Czechoslovak construction industry does not have very extensive practical experience in this type of construction.

/During the Sixth Five-Year Plan the construction industry began to assert itself more on foreign markets, primarily in the socialist countries in the construction of oil and gas pipelines, the electrification of railroad lines and even in industrial and residential construction. The mastery of these tasks was on a high level, and in national economic terms contributed to providing raw materials and especially natural gas for the Czechoslovak economy. At the same time, it was confirmed that construction capacities are an export commodity which is in demand and that a slowing of the pace of investment creates some leeway for using capacities on external markets./

The technical and economic level of the Czechoslovak construction industry is competitive in world markets, and in carrying out this year's plan and preparing for 1981 the possibility of export to both socialist and nonsocialist countries, as well as the resultant economic advantages for our national economy, must be examined. The state plan creates possibilities for expansion of export activity, primarily for the Ministry of Construction and specialized capacities of the federal ministry of fuels and energy.

Even given the rapid pace of the export assignments, their share in the Fifth Five-Year Plan did not achieve even 1 percent of the total capacity

of the contractor organizations in capital construction. During the Sixth Five-Year Plan it is expected that this value will be exceeded, and the possibilities for the Seventh Five-Year Plan period are as high as approximately 4 to 5 percent.

Performance of export tasks has its own unique characteristics and differences from export of industrial products, particularly in the fact that it requires transfer of workers. In addition the forms for carrying out production projects in the nonsocialist countries, where it is possible to hire manpower, differ from those in export to socialist countries, where it is necessary to use one's own resources.

Effective export of construction work requires mastery of both the technical and organizational aspects. This entails creating the preconditions in prospective population centers by building a social and production base and concentrating the export tasks in the construction organizations which have the technical and manpower capabilies needed. Thus this involves the area of utilization of construction capacities, which previously lagged behind the tasks of domestic capital construction. Past experience indicates that the need to develop, within comprehensive socialist economic integration, not only scientific and technical cooperation, but also specialization and cooperation in supporting the investment programs of the CEMA countries with construction capacities, has become pressing.

The system of balanced utilization of construction capacities for the needs of capital construction in the national economy together, as well as for export, has been described in some detail as regards state plan indicators, which are broken down and made specific by supplier-purchaser relations in the construction enterprises' production programs. However, in addition to the contractor construction organizations, organizations engaged in construction work which are not included in the plans for contractor construction organizations, i.e. nonconstruction organizations, also take part in capital construction.

Their share in meeting capital construction requirements is as follows:

Location	Indices		Percentage of total amount of work		
	1980/1975	1975/1970	1980	1975	1970
CSSR					
construction organizations	127.1	143.8	77.4	73.5	71.2
nonconstruction organizations	103.6	117.9	22.6	26.5	28.8
CSR					
construction organizations	124.8	141.6	75.9	70.9	68.2
nonconstruction organizations	95.0	115.3	24.1	28.1	31.8
SSR					
construction organizations	131.3	148.0	80.2	78.6	77.6
nonconstruction organizations	122.1	125.4	19.1	21.4	22.4

The development of contractor construction organizations creates preconditions for gradually increasing their share of the total quantity of capital construction, even though it must be taken into consideration that there is a rational limit to the division of labor between these two areas of its performance. The utilization and distribution of the capacities of nonconstruction organizations is specified in the construction work balance for each central investor, so that it is reduced to financial support of capital construction by the direct investors. Both contractor construction organizations and nonconstruction organizations, which are an inseparable part of the sources of construction work in the national economy at the level subject to balancing, must be included in the monitoring of plan fulfillment.

/Satisfaction of the requirements of capital construction by construction capacities with the required breakdown also involves cooperative relations between construction and nonconstruction organizations, particularly involving subcontracted supply of the special construction work on which depend smooth construction progress and on-schedule completion of projects (high-voltage and low-voltage wiring, ventilation and air conditioning). In its decree on the plan for 1980, the CSSR Government imposed the task of meeting the needs of the construction industry, particularly for projects approaching completion or priority projects, so that it would be informed regarding performance of this task./

The balance system for construction work fully covers expanded reproduction of capital assets. As regards repairs of long-term assets, buildings and structures, these needs are covered by both contractor construction organizations and nonconstruction organizations. The state plan assigns the contractor construction organizations a quantity of repair work; the breakdown of this work during the Fifth and Sixth Five-Year plans developed as follows:

	Index 1980/1979	Average annual pace, Sixth Five-Year Plan	Share of total amount of work, %		
			1980	1975	1970
Total construction work on repair projects	104.0	2.8	100.0	100.0	100.0
Done by organizations managed by:					
federal bodies	104.6	0.0	3.8	4.3	4.4
CSR and SSR ministries of construction	99.9	2.8	23.7	23.7	17.0
CSR and SSR national committees	105.3	2.8	71.6	71.3	77.6

As indicated by the percentages, division of labor at the sector level is stable, as is the breakdown of the repairs conducted. The pace of development in the Fifth Five-Year Plan surpassed the planned levels, particularly in work on capital construction. One of the main causes was the carrying out of so-called major repairs on the power grid, the quantity of which was limited in the Sixth Five-Year Plan. We may expect that overall, construction work on repair projects will surpass the planned quantity in the Sixth Five-Year Plan.

The basic approach to the plan for 1980 is rational utilization of these capacities in the context of planned reserves. Meanwhile, an outflow of capacities to the areas which weaken capital construction is undesirable, particularly in organizations belonging to the construction ministries. The current situation requires maximum concentration of capacities on priority investment programs and on completion of projects. To adjust supply and demand in repair work, the capacities of the nonconstruction organizations, which have a slower pace in capital construction, may be used.

Construction work on repair projects is a serious national economic problem. The need for it stems from the development and the structure of capital assets, buildings and structures in the national economy. Performance of repair work, however, entails raising the technical-economic level of its performance, which requires that a technical policy also be worked out for this field, which is making increasing manpower demands. The low technical level of this work is affecting the meeting of current needs.

The participation of construction organizations in both repair work and private capital construction is consistently low in terms of deliveries to the public. With demand exceeding their capacity, the construction organizations are not adequately meeting the needs of the public. Accordingly, in addition to reproduction of capital assets and export, the construction industry is also faced with the task of meeting the public's needs for construction work.

Meeting the needs of capital construction on time, i.e. completion of projects, is emerging as a problem of the structural development of construction capacities. The 15th KSC Congress assigned the task of decreasing the level of uncompleted construction and shortening the average duration of projects by 15-18 percent by the end of the Sixth Five-Year Plan, and the Sixth session of the KSC Central Committee mapped out the task of resolving the inconsistency between the relatively rapid progress of construction in gross terms and the long periods required for completion of projects. This is a task which is not successfully being mastered and whose accomplishment will stretch over into the next five-year plan.

/To carry out the 1980 plan as regards completion of construction projects and concentration of capacities on priority projects, it is also

necessary to proceed in terms of the starting base for the Seventh Five-Year Plan, particularly in connection with the structural development of construction capacities and completion of the construction cycle. The preconditions for decreasing the amount of uncompleted construction are provided by the state plan, by limiting the number of construction starts. The construction industry has the task of adapting itself to these structural changes by reorganizing enterprise capacities./

To decrease the amount of uncompleted work and to complete projects, the state plan assigns the contractor construction organizations specific quanitities of construction work on projects to be completed in the planning year and issues directives regarding concentration of capacities. These are interconnected instruments; the directives on concentration limit construction starts, and specification of amounts of work on projects slated for completion creates an economic pressure to get the projects into operation.

The plan specifies, for the Czech and Slovak ministries of construction, volumes of construction work on projects which are to be completed in the year covered by the plan. The long-term development of the share of this figure in the total amount of work on capital construction is as follows:

	Indices		Billions of korunas		
	1975/1971	1980/1975	1971	1975	1980
CSR Ministry of Construction					
on capital construction	133.7	130.4	17.2	23.0	30.0
on projects to be completed within the year	230.0	113.0	2.0	4.6	5.2
SSR Ministry of Construction					
on capital construction	137.4	136.1	10.7	14.7	20.0
on projects to be completed within the year	188.2	106.3	1.7	3.2	3.4

In the Fifth Five-Year Plan, both ministries had a considerable increase in work on projects to be completed within the year of the plan, while in the Sixth Five-Year Plan this increase has been slowing and is characterized by a decreasing share of this work in the total quantity of capital construction. Analysis reveals a number of causes, involving both the contractors and the investors, but the common denominator is a falling behind in construction completions, with which is associated a falling behind in the development of capacities for completion of work, and their nonuniform use during the course of the year.

Although guidance of the development of capacities toward the completion cycle is stimulated by enterprise and personal incentives, nonetheless the results achieved are not satisfactory. It appears imperative to test and develop new approaches in connection with the evaluation of enterprises, not in terms of fulfillment of volume indicators, but in terms of completion of projects and handing over of completed work for use. The designation of a quantity of work for completion in the annual plan, possibly with an annual increase included in the directives, is too short-term a measure to orient capacity and cannot do much to work out the needed structural development. In essence, it can only seek ways to step up completions within the context of existing uncompleted projects. This is relatively little leeway, as is also shown by the results achieved. For the state plan, in which the basic economic dependencies are to be expressed, the inclusion of an annual quantity of work on projects designated for completion is more rational than norms on uncompleted construction, since it would set an assignment for completions on a long-term basis in relation to the pace of development of construction capacities and the decrease in the number of uncompleted projects.

In addition to the assignment for completions, which is set in absolute value terms, the organizational support of the plan provides directives on concentration of construction capacities on a smaller number of projects currently under way, and the average number of workers per project, which is the decisive factor for concentration of construction machinery and equipment as well, is chosen as a measure of this. In order to increase the concentration of construction capacities on a smaller number of projects currently under way and gradually to decrease construction times, the contractors' central offices are ordered to have their subordinate organizations set maximum limits on the number of construction starts, which they will determine in such a way as to effect an increase in the concentration of workers on projects of 8-12 percent over the 1979 plan (in the 1979 plan the assignment for concentrating workers on projects was set at 8-12 percent), also specifying the number of projects to be completed and budget expenditures on them.*

In carrying out the plan, this directive must be fully adhered to, and in addition it must be stressed that it applies to all construction enterprises in the sector and may not be narrowed to enterprises manged by the construction ministries. Another of the current shortcomings of sectoral management is the fact that approaches and solutions are not always implemented throughout the sector, which increases the differences in technical and economic levels between individual enterprises and departments within the sector.

---

*An analysis of this problem and a calculation method were given in the article "Concentration of Construction Capacities to Deal with Uncompleted Construction," PLANOVANE HOSPODARSTVI Nos 3 and 4, 1979.

/The construction industry's main tasks in the 1980 plan have now been summarized. Their accomplishment must be approached as representing the creation of the starting basis for the next five-year plan, and monthly and quarterly plan fulfillment at all economic management levels must be analyzed from this angle. The main criterion is substantive fulfillment of the planned tasks, and the plan may no longer be considered as fulfilled when only the total quantity of work conducted with one's own workers, i.e. ZSV value, is achieved./

The state plan charges the construction industry with accomplishing the substantive tasks, and it uses its system of priorities to orient the development of construction capacities in accordance with the requirements of the capital construction plan, and does not place achievement of gross or overall or aggregate value indicators in the forefront. On the basis of the organizational support of the 1980 plan, each construction enterprise is assigned a range of indicators in the areas of breakdown of sales, proportion of expenditures on adjusted output and technical development, whose fulfillment is a basis for evaluation of plan fulfillment and which cannot be narrowed to aggregate indicators.

[No 6, 1980, pp 43-57]

[Text] At the conclusion of the Sixth Five-Year Plan and before the entry into the Seventh, the construction industry has received new economic conditions which require that in many areas it change traditional views of its development, not only in the stage of carrying out capital construction, but especially in the stage of planning preparation. The fulfillment of the 1980 plan must also be judged from this angle, for it creates the base for smooth mastery of improved utilization of inputs both in the production process and in the phase of design and manufacture of intermediate products, in which there is critical potential for new technical and process solutions.

/Rationalizing the conduct of work on construction projects can lead to only part of the needed savings on metal, fuels and energy. The critical effect must be sought in design decisions, which will respect hard-to-obtain materials and products and try to replace them with materials and products from the domestic raw materials base. In securing approval of design documentation, the supplier and designer must base themselves on the real production base. Design preparation this year will determine consumption in the second half of the Seventh Five-Year Plan, from which it follows that approaches oriented toward adherence to the above-mentioned national economic limitations for development of the construction industry, and thus for performance of capital construction, may not be narrowed, even in the stage of performance of the construction project. Only mastery of the entire investment cycle from preparation of the investment project to handing over the facility for permanent use can bring about a turnaround in previous, frequently burdensome, design demands for hard-to-obtain materials and products./

For example, the national economy, and accordingly the construction industry, has sufficient large-diameter pipeline material and extensive possibilities for substitution of alternative materials (steel, cast iron, plastic, reinforced concrete, prestressed concrete), but nonetheless for a number of years the use of steel pipes from Podbrezov has become more intensive, although it has long been known that the output of these will not increase. The systematic failure to balance demand against real supply is leading to hitches in capital construction, conversion of design documentation to other materials, and as a result prolongation of construction time. The use of pipe from Podbrezov unquestionably has technical and economic advantages, and under some technological conditions it has irreplaceable characteristics, but given the situation with regard to supplies of piping materials, a realistic technical solution based on the capabilities of the national economy must be agreed upon between supplier and esigner in the design preparation stage. This will not excuse inadequate adaptability (structural changes) of the material producers to the characteristics required for construction effectiveness.

It would be possible to cite further examples, but the purpose is only illustration and correct understanding of the idea of relations between the investor, designer and contractor, faced with limited material inputs to the construction industry. It thus proves essential to connect them rather consistently and to reconsider the current division of labor in planning preparation of construction projects so that the working plans will be developed by the construction contractor. This involves extremely complex system relationships, whose efficiency has already been investigated many times; and it is useful to turn to them again in regard to connecting the processes for performance of construction projects with the real material-technical base of the construction industry. Obviously, other factors too are operative here, which we need not further enumerate in connection with the problems of the 1980 plan.

In keeping with the balanced supplies of construction work in the national economy, the development of the capacities of construction organization has been specified in terms of the value of work conducted by an organization's own workers (ZSV):

	Indices of ZSV development			Meeting the increase in ZSV with increased labor productivity		
	1975/1970	1980/1975	1980/1979	5th FYP*	6th FYP	1980
CSSR as a whole	150.1	128.8	103.8	71.5	82.6	94.7
federal organizations	151.0	115.7	99.8	66.3	62.4	99.5
CSR and SSR ministries of construction	150.7	134.1	104.4	70.0	81.5	93.2
organizations managed by national committees	149.2	121.1	103.9	78.8	91.9	100.0

*five-year plan

The degree to which labor productivity provides for increases in production will gradually increase in the next decade; the level established in the 1980 plan assumes an increase of 1,800 workers in the sector. The exhaustion of manpower reserves in the national economy and the expected pace of investment in the next five-year plan present the construction industry with the task of providing the full increase in output through an increase in labor productivity. With its relatively small increase in comparison with previous years, the 1980 plan is the beginning of a new stage in the development of the construction industry, lacking an increase in manpower; this is not a reflection of current interest in employment in the construction industry, as frequently appears in discussions of the increase in the number of workers in relation to planned tasks.

During the last 10 years, employment in the construction industry has been characterized by a drop in absolute growth. In the Fifth Five-Year Plan, an increase of 51,225 workers was achieved, exceeding the planned value of 17,290 by a total of 33,935 workers. The turning point came during the Sixth Five-Year Plan. The planned increase in the number of workers was fulfilled as follows (in thousands of workers) during the gradual decline:

	1976	1977	1978	1979	1980
Sixth Five-Year Plan	545	553	555	561	565
Annual increase	8	8	2	6	4
Actual	542	551	554	557	559*
Annual increase	5	9	3	3	2*

In spite of difficulties in finding workers for the construction industry it is expected that fulfillment of the Sixth Five-Year Plan will amount to 22,000 of the planned figure of 28,000 workers, which is reflected in the last year in an average worker complement which is 6,000 workers low.

/The growth of construction capacities in the Seventh Five-Year Plan is based on the planned complement of workers in 1980, with the increase in output being met by an increase in labor productivity. This requires that this year, in addition to more efficient utilization of available workers, the distribution of workers in the various activities of construction enterprises be reevaluated; what is especially involved is a relocation of workers into production processes in the construction projects and into secondary activities. The essence of this situation is that even with an increase in manpower the plans for workers in the trades, particularly in certain specialties at the construction sites, were not fulfilled, and it was necessary to fulfill them by means of imports./

*annual plan

The structural transformation of capacities during the Seventh Five-Year Plan is associated in particular with a strengthening of the enterprises engaged in industrial and engineering construction, and requires solution of the problem of placement of workers, and of the associated problem of division of labor within the construction sector and between the construction industry and the other sectors of the national economy. The demanding nature of the task lies in the fact that the structural conversion must be carried out during a stagnation in the number of workers throughout the five-year plan, essentially at the 1980 level. Accordingly this problem must be analyzed profoundly and a solution sought within the designated manpower limitations.

The increase in the number of workers in the construction industry and in its basic activities has been as follows (in thousands):

	Total workers	Workers engaged in construction	Manual	Operations and service	Other	Workers in auxiliary operations
Initial breakdown of workers in 1950	325.4	276.1	226.7	12.0	37.4	49.3
Increase in:						
First Five-Year Plan	46.7	31.5	15.5	2.7	13.3	15.2
Second Five-Year Plan	71.1	49.7	37.0	1.4	11.3	21.4
Third Five-Year Plan	0.3	-3.2	-8.6	0.5	4.9	3.5
Fourth Five-Year Plan	42.0	30.3	15.2	1.4	13.7	11.7
Fifth Five-Year Plan	53.0	32.9	19.0	3.0	10.9	20.1
Annual increase:						
1976	5.9	1.7	-1.2	0.6	2.3	4.2
1977	7.3	3.5	1.8	0.3	1.4	3.8
1978	3.3	0.6	-0.3	0.3	0.6	2.7
1979	3.4	-0.1	-0.6	0.4	0.1	3.6

Hitherto the growth of construction capacities depended on a rather rapid increase in the number of workers, which made it possible to handle structural changes within its scope with virtually no interference with enterprise breakdowns.

In the Third Five-Year Plan there was a drop in the number of workers in construction, which began in 1961 and continued through 1962 and 1963. The turnabout came in 1964, and the 1962 number of workers was first exceeded again in 1966. The movement of workers out of the construction industry, which resulted from a loss of preference accorded to this sector, had to be dealt with by extraordinary measures in wages and

social policy. Instructive in this connection is the fact that renewing interest in work in the construction industry is a long-term process. Similar symptoms have been observable in the current five-year plan as well, and their result is a shortage of workers with certain skills in the construction projects.

/Leeway for structural transformation of construction capacities in keeping with the requirements of capital construction must also be sought in more efficient allocation of workers between primary construction work and the secondary operations, and within the latter. Accordingly, it is advantageous to characterize past development in more detail. Over the long term, the structure has developed in the direction of an increase in the percentage of workers in secondary operations from 15.2 percent in 1950 to 22.5 percent at the end of the Fifth Five-Year Plan, with a trend to faster and faster growth. In 1979 the figure was already 24.5 percent./

Within the primary activity, the percentage of operations and service workers is gradually increasing, and the percentage of technical operations workers is growing, while the percentage of manual trades workers at the projects decreases.

Year	Workers engaged in construction work	Trades	Operations and service workers	Other workers
1950	100.0	82.1	4.3	13.6
1955	100.0	78.7	4.8	16.5
1960	100.0	78.2	9.5	17.3
1965	100.0	76.4	4.7	18.9
1970	100.0	74.3	4.7	21.0
1975	100.0	73.0	5.0	22.0
1977	100.0	72.3	5.2	22.5
1978	100.0	72.1	5.3	22.6
1979	100.0	72.0	5.4	22.6

The changes in the breakdown of workers in construction work reflect the industrialization of the construction industry, particularly the introduction of the prefabricated and fully assembled construction technologies and the increased share of mechanization and comprehensive mechanization of construction work, as well as the associated demands on management and organization. It is necessary to determine the degree of this effect and the corresponding required number and breakdown of workers in construction work.

A criterion of an effectively structured increase in the number of workers in construction is substantive fulfillment of the state plan tasks. Among the primary causes for nonfulfillment we may cite shortages in certain construction trades, and enterprise plans too are not being fulfilled in terms of structural indicators. Thus the breakdown of workers is not

in agreement with the needs of structural development of construction capacities. The pressure to end this disproportion is increasing, because it involves the activity which consumes the greatest amount of labor value added. When the planned development of capacities is based only on increased labor productivity, the problem becomes even more acute. It cannot be put off to the Seventh Five-Year Plan: it requires consistent solution even during performance of the 1980 plan, which must prevent further divergence between demand and the supply of construction trades.

In the Fifth and Sixth Five-Year Plans, the structural disproportion between construction capacities and trade breakdown of the workers was made up by import, in the form of:

/-importing turnkey projects;
-subsupply for general contractors of projects;
-import of building trades./

In connection with the development in the Fifth Five-Year Plan, a gradual elimination of both direct import and import of trades has already been achieved in the sixth.

The belated reaction to the unfavorable structural development of the building trades, together with inadequate regulation of the increase in number of workers on projects, showed themselves systematically in a pressure to import trades, which further increased the need to concentrate some trades (carpenters, masons, scaffolders, plasterers) on selected projects, particularly the nuclear program, hydraulic and thermal power stations, metallurgical facilities in the North Bohemian Kraj, projects in the "third area" and comprehensive housing construction in Prague.

The share of imported construction work in the total quantity of capital construction in the national economy is relatively small (for the Sixth Five-Year Plan), amounting to about 2 percent of the work done by contracting organizations in capital construction, and is continuously decreasing. Imported building trades averaged about 1,000 workers a year with a falling trend. The demand for these imports stemmed from the long-term unfavorable development of the worker breakdown, which was not consistently regulated in keeping with national economic goals. As the imports are eliminated, the Czechoslovak construction industry has considerable leeway for matching supply to demand through domestic resources, by the first year of the Seventh Five-Year Plan at the latest.

The approaches to evaluating the previous unfavorable development of the worker breakdown in the construction industry may not be simplified, because they are also associated with the nature of employment in this sector (separation from family, transfers to key projects and to areas of concentrated capital construction, work under difficult weather

conditions), and this during full employment and a high standard of living for all workers in the national economy. Bringing workers into the construction industry, keeping them and training them in the required range of trades is and will be one of the most demanding tasks of organization and management work in the construction industry.

/Concentrated attention must be devoted to this problem in the 1980 plan in terms of both skill structure and comprehensive creation of the conditions for keeping the workers. Hitherto a high level of worker turnover amounting to roughly a third of the total labor force and systematic overflow between enterprises and departments has decreased the efficiency of manpower utilization and failed to provide a firm foundation for an increased level of organizational work. This problem must be dealt with in the context of the planned reserves, and import of building trades can no longer be planned in order to make up for fluctuations./

At the 14th plenum of the KSC Central Committee, an unequivocal directive was issued to the construction industry that its development of the trades structure should make it possible with the utmost speed to provide the imported building trades and construction capacities from our own resources. The import of construction work ended, other than agreements already concluded, and the import of building trades will continue only within strict limits. The CSSR Government has discussed the elimination of import of building trades and has ordered the construction ministries to develop a comprehensive program to supply the needed range of trades.

In the 1980 plan the increase in the number of workers must already be so regulated that the trades in particular are strengthened, both by recruitment of manpower and by its redistribution among the internal resources and construction enterprises. This will create the basis for retraining and further training of workers in the required trades.

On the basis of previous development and experience which confirms that training and instruction of workers is a long-term process, the CSSR Government has directed that a trades management system be developed at the enterprise, VHJ and department level; this must be in keeping with current capabilities and manpower resources. At the same time, the conditions are being created for utilizing the trades which are in shortest supply by concentrating them on key projects, by developing specialized teams led by experienced technicians and by bringing these to bear smoothly and using them on the basis of time schedules. This thus involves an approach which increases organization and management of workers above the level of a single project, and possibly above the level of enterprise and VHJ. Making these organizational measures effective requires a greater availability to the workers of construction machinery and equipment; this will by no means be based solely on demands for new machinery, but will come primarily by improved utilization, with a decrease in the amount of uncompleted construction.

In order to speed up the matching of the supply of trades in short supply to the demand, measures have been adopted whose fulfillment is among the basic tasks for 1980, particularly as regards creating the conditions for elimination of these disproportions in the very first years of the Seventh Five-Year Plan.

Specific tasks in the training of unskilled workers as assistants in carpentry and tiling work have been assigned. In addition, wage bonuses have been established for bringing workers into training and retraining as carpenters and tile-layers, and the limits for personal evaluation and the length-of-service bonus after at least 5 years have been increased.

Management of the development of the trades structure in accordance with the capital construction program requires development of a system for monitoring of long-term regulation of trades development in connection with the structural changes in the production program and trends in production technology and the total number of workers.

In connection with achieving an increase in construction output by increasing labor productivity, stress is laid on the need to reevaluate the existing distribution of workers in the construction industry. We refer in particular to workers engaged in construction and workers in secondary operations, whose share amounts to about 25 percent.

The secondary operations of construction enterprises have developed under conditions of the industrialization of the construction industry and development of social division of labor, not always effectively utilized, and with an inadequate utilization of the economic advantages of concentration and specialization of production within departments and sectors. The level which has been achieved also requires that all capabilities be used in this area to increase construction efficiency in relation to the 1980 plan and the preparation of the Seventh Five-Year Plan.

The varied nature of the activities of secondary operations requires a differentiated approach, both as regards effective meeting of the requirements of construction and in relation to the economic environment, particularly the provision of deliveries and services by the other sectors of the national economy. The current status and developmental trend of secondary operations of the construction enterprises in the Czechoslovak construction industry can be expressed in terms of the following breakdown of workers (in thousands):

	1975	1976	1977	1978	Increase in number of workers by year 1976	1977	1978
Secondary operations as a whole	120.0	124.6	129.3	132.3	4.6	4.7	3.0
Industry	44.6	46.3	48.0	49.5	1.7	1.7	1.5
Transport	46.5	48.4	49.6	50.3	1.9	1.2	0.7
Planning	7.2	7.5	8.2	8.3	0.3	0.7	0.1
Material and technical supply	1.2	1.0	1.0	1.0	-0.2	--	--
Plant dining rooms	1.7	1.8	2.0	1.9	0.1	0.2	-0.1
Other production activities	1.4	1.5	1.4	1.4	0.1	-0.1	--
Research and development	1.9	2.0	2.0	2.1	0.1	--	0.1
Housing and domestic	5.6	5.5	6.1	6.2	-0.1	--	0.1
Personnel training	5.9	5.9	6.0	6.0	--	0.1	--
Machine computation stations	1.2	1.4	1.6	1.7	0.2	0.2	0.1
Enterprise health services	0.1	0.1	0.1	0.1	--	--	--
Other departmental activities	2.7	3.2	3.3	3.8	0.5	0.1	0.5

Industry and transport have the greatest weight, with shares of 37.4 and 38 percent respectively. Far behind are planning (6.3 percent), the housing services and residential operations (4.7 percent), and manpower training organizations (4.5 percent) while the remaining activities account for less than 10 percent.

The increase in the number of workers during 1975-1978 was basically directed to the production, transport and project planning areas: 4,900 for the building materials industry, 3,800 for transport, 1,100 for planning and 700 for housing and personnel training services.

The structure of secondary operations in the construction sector differs considerably in individual enterprises of the relevant central organs according to the nature of their work, the degree of development of cooperation and additional factors which affect the need for particular activities. Accordingly we cannot introduce specific conclusions for the enterprise level on the basis of a sectorwide viewpoint without specific balancing of demand and supply of products and services for smooth construction progress, as well as the meeting of the construction industry's needs by the other sectors of the national economy.

/From partial findings, however, we may conclude that the material production base and services within the secondary operations of construction

enterprises have dispersed capacities with low work efficiency, result- from the relatively small-series nature and variability of a production program which is specified on an as-needed basis to assure smoothness of construction work. The basic route to making these activities more efficient is their sectoral integration in connection with intersectoral division of labor, particularly in relation to the machine-building industry. The construction of these comprehensive production and service bases has already been begun in areas of concentrated capital construction, particularly in Prague and the North Bohemian Kraj. During the Fifth and Sixth Five-Year Plans a substantial part of the required social and production base was implemented./

The development of construction enterprises' secondary operations has a consistently rising trend, and their direct relationship to primary construction activity and to the overall efficiency of construction requires planned management not only at the department and operating organizational level, but in the sectoral structure as well. Accordingly, the relevant indicators were included in the Unified Procedural Directives for Developing Five-Year and Annual Plans; these make it possible to proceed to a central solution of the problem of efficient development of these activities. The decisive role among these activities goes to the building materials industry, which breaks down as follows according to number of workers:

	1976	1977	1978	Indices 1977/1976	Indices 1978/1977
Total industrial production and production-support construction	100.0	100.0	100.0	100.1	101.5
Production-support construction work	17.7	15.4	15.1	87.4	99.6
Production construction components	28.5	29.4	29.1	103.0	100.4
Rock quarrying and processing and preparation of light fillers for concrete	1.8	1.7	1.6	93.4	95.5
Production of metal structural members and fittings	14.5	14.0	13.9	96.8	100.5
Repair of construction machinery	30.3	31.9	32.9	105.4	104.5
Production of carpentry and woodworking products	2.3	2.3	2.3	101.2	102.4
Other industrial production	4.9	5.3	5.1	108.1	99.0

Each of the above types of production has its own specific characteristics, requiring its own approach to increased efficiency, both at the enterprise level and in the context of specialization and cooperation. On the

basis of an independent analysis of the efficiency of development of prefabrication, measures have been adopted in the 1980 plan to increase the efficiency of production of structural components. The construction organizations have proved to be using these production bases inefficiently, and accordingly labor productivity has been stagnating even as equipment has increased. The significance of these measures lies in the fact that a significant proportion of the production of construction components is concentrated in the construction enterprises. Of the total capacity under the ministries of construction, about 35 percent is incorporated organizationally into the construction enterprises, while the remaining 65 percent is in the Prefabrikace VHJ, i.e. in the building materials industry.

In order to increase the level of planned management of this important supporting area, as part of the organizational support for the 1980 plan the Czech and Slovak construction ministries are ordered to establish assignments for developing the production of silicate prefabricates, organized at the construction organization level with the following indicators:

/--output in physical units;
--adjusted output;
--labor productivity;
--number of workers;
--ratio of material expenditures to adjusted output./

Also required is documentation and monitoring of the fulfillment of the tasks assigned.

The production of silicate components is specified in some detail because it is a named assignment in the plan for 1980 to whose fulfillment concentrated attention must be given, and the findings from which will be used as the basis for improving planned management of construction enterprises' secondary operations.

In carrying out this year's plan and preparing the 1981 plan and the Seventh Five-Year Plan, the secondary activities of the construction enterprises must be expanded only on a scale which will assure smoothness in the construction process. The development of the individual activities in subsequent years will achieve varying economic results. Construction work in support of production processes will develop the most rapidly as regards total output (and also in labor productivity in reaction to a drop in the number of workers), in accordance with the implementation of technical progress and will achieve the required relative savings of workers (production in central concrete, mortar, steel reinforcing rod and crushed-stone plants, and the like).

The shortage of repair capacities in specialized organizations requires that in addition to technical and preventive maintenance, building

industry production also carry out medium repair and general overhaul of machinery and transport facilities. According to estimates, the repair shops of construction organizations will carry out about 50 percent of the repair work. With dispersed capacities and a shortage of spare parts, their efficiency is low, as indicated by their increasing number of workers.

The construction enterprises are carrying out the production of about half of the fastenings and fittings used, while the rest is produced on site or delivered from production facilities outside the construction enterprises. Increased efficiency must be combined with concentration of production. Similarly, analyses must be made of secondary activities, and not only in the building materials industry. When seeking ways of increasing construction efficiency, the focus of attention should be secondary activities which have fallen below the technical, organizational and management level of primary construction work, which will make it possible to increase output with lower investment expenditures than in primary construction work.

Plant transport has a special position in construction enterprises' auxiliary operations; its large increases in number of workers must be evaluated in connection with transport output. The nonproduction activities also meet the need for workers for the housing services, training work and plant dining rooms, as specified by the relevant regulations, even though there are ways of economizing in this area.

The development of construction enterprises' secondary operations has reached a level requiring comprehensive sectoral analysis in terms of the possibility of increasing the effectiveness of manpower utilization in the construction industry, which in many cases is limited only in construction work itself, i.e. in decreased labor intensiveness at the construction sites. This narrow conception of rationalization, directed only toward work on the construction site, does not embrace all possible ways of improving the efficiency of secondary activities, which must be discovered in concentration and specialization of production, supra-enterprise service activities and rationalization of intersectoral division of labor. Here it must be stressed again that the development of the construction industry in the Seventh Five-Year Plan is based on increased labor productivity with essentially no increase in the number of workers over the level achieved in 1980. This requires that a structural transformation of construction capacities be carried out throughout the production and nonproduction activities of construction enterprises.

Creation of conditions for a smooth transition from the Sixth to the Seventh Five-Year Plan is essential in 1980, and this cannot be separated from fulfillment of planned tasks and preparation of the plan for 1981. This entails not only a problem of the construction industry itself, but also a problem of the national economy, for it is growing into a

question of working out intersectoral division of labor, particularly between the construction industry, the machine-building industry and other sectors of the national economy. Assuring deliveries of materials and products from these sectors is a precondition for limiting less efficient production activities in the construction enterprises.

/The 14th plenum of the KSC Central Committee assigned first place among the principal tasks to consistently assuring the planned increase in production with limited inputs and ordered that the maximum attention be devoted to conservation in the consumption of petroleum products./

/The construction industry is one of the sectors of the national economy which has a high consumption of fuel and energy, both in its own production process and in the range of building materials, other materials and parts which it consumes. The quality and the thermal engineering parameters of exterior facings determine fuel and energy consumption when buildings are in use. Thus we should briefly identify the areas in which is is necessary to work out programs of measures to reduce fuel and energy consumption in carrying out capital construction, in all phases from manufacture of semifinished products to the handing over of high-quality construction work./

In view of the limited sources of motor fuel, currently top priority belongs to provision for deliveries in the construction industry, particularly given the increasing technological complexity of the projects (construction of nuclear power plants, hydraulic engineering products on the Danube, mains, transport projects and the like). The construction process is highly transport-intensive; the breakdown of transport for construction work and the building materials industry is developing as follows:

	1970	1975	1980	Indices 1975/1970	Indices 1979/1970
Total transport	100.0	100.0	100.0	138.4	163.8
Plant motor transport	59.7	61.2	66.4	143.1	182.1
CSAD motor transport	27.1	27.0	24.0	137.8	144.9
Railroad transport	8.8	7.3	6.2	115.7	116.8
Water transport and other	4.4	4.0	3.4	123.2	124.4

The critical element is motor transport, whose share increased from 86.8 to 90.4 percent during the last decade; as transport by CSAD [Czechoslovak Motor Transport] has dropped, the share of plant motor transport has increased greatly. Under current conditions, we must justify the level of motor transport in terms of maximum conservation of motor fuel. Accomplishing the planned tasks under the specified limitations on motor fuels requires a decrease in consumption when operating transport

facilities; another route is an absolute decrease in transport tonnage and transport output in connection with the real possibilities for meeting the requirements with other means of transport.

At present there are no technical indicators which provide sufficient information in justifying the amount of transport tonnage and transport output in the construction industry. On the basis of partial findings from construction projects, we may conclude that there is excessive use of transport, particularly construction-related transport of soil. The fuel limitations will help curb this increase, which manifests itself among the construction contractors with all its economic and technical consequences as regards carrying out projects, but has no direct effect on investment and planning preparation.

Motor transport provides a critical amount of work for construction enterprises; the relationship between plant and public transport is organized by plan in such a way that together they meet the overall needs. In the Sixth Five-Year Plan, the motor transport requirements of enterprises in the construction industry (in tons per million korunas of construction work) showed the following development and structure:

	1975	1976	1977	1978	1979	Index 1979/1975
Total						
millions of tons	492	530	546	568	806	123.2
tons/million Kcs ZSV	11,765	11,643	11,307	11,071	11,371	96.7
Earth						
millions of tons	213	230	264	275	296	139.0
tons/million Kcs ZSV	5,095	5,052	5,467	5,360	5,554	109.0
Building materials						
millions of tons	211	233	282	292	310	146.9
tons/million Kcs ZSV	5,047	5,052	5,840	5,711	5,817	115.3

With the total tonnage of all transport up 18 percent between 1959 and 1979, and with the indicator of tons per million korunas of construction work down by 1.1 points, motor transport is expanding.

In the breakdown of materials carried, the share of earth and construction materials is increasing, and transport of other materials is decreasing. The amounts of earth and construction materials carried at the beginning of the five-year plan were roughly the same, i.e. earth-moving work requires just as much transport as construction itself, or in other words the tonnage of earth carried is essentially equal to that of construction materials carried, both per million korunas of construction work and in absolute terms. The weight of construction materials

carried is gradually increasing, but these are only rough calculations, for they take in only motor transport by the plants and by Czechoslovak State Truck and Bus Transport.

According to the tonnages indicated, each million korunas of constructionn work accounts for about 5,800 tons of building materials. The material-intensive nature of construction is determined by construction technology, and in this context a long-term task is to decrease it, particularly in the stage of planning preparation. Another way of decreasing the transport requirements lies in construction organization and management. This involves particularly a decrease in the number of intermediate depots and in excessive transfers and haulage, rationalization of on-site transport and the like. For a rough estimate we can use the example of the material-intensiveness of residential construction, which from this viewpoint is a demanding type. With an average material consumption of 95 tons per housing unit, each million korunas of construction work in this area of capital construction calls for 760 tons of building materials. Comparison of this number with the average amount of transport per million korunas of construction work allows us to judge the extent of necessary and realistically possible savings from the current level. At the same time, it must be taken into account that the amount of building materials transport mentioned includes the building materials industry.

Another important consideration for conservation of fuels is the number of ton-kilometers of haulage by plant motor transport, where conservation and the meeting of transport requirements within the supply limitations are critical for assurance of a smooth construction process.

Plant motor transport can be characterized by the following basic indicators of transport tonnage and transport output in relation to the quantity of work carried out by internal resources (ZSV):

	1970	1975	1976	1977	1978	1979	Indices 1975/1970	Indices 1979/1975
Total								
tons/million Kcs ZSV	8,618	8,189	8,113	7,987	7,966	8,337	95.0	191.8
Earth								
tons/million Kcs ZSV	3,506	3,715	3,741	3,688	3,869	4,090	106.0	110.1
tkm*/million Kcs ZSV	9,209	10,677	11,437	12,394	13,152	15,082	115.9	141.3
average transport distance, km	2.6	2.9	3.1	3.4	3.4	3.7	111.5	127.6
Building materials								
tons/million Kcs ZSV	3,232	3,200	3,089	3,156	2,988	3,070	99.0	95.0
tkm/million Kcs ZSV	36,064	34,976	34,326	35,396	35,633	36,693	97.0	104.9
average transport distance, km	11.2	10.9	11.1	11.2	11.9	12.0	97.3	110.1

It is typical of plant transport within this department (for construction and building materials industry enterprises) that more than half of transport tonnage is accounted for by moving of earth.

The average transport distance for building materials decreased during the Fifth Five-Year Plan. Currently, however, it is moving up, having increased by about 10 percent; thus we have a decrease in both transport tonnage and transport output in ton-kilometers. In this connection it is necessary to increase also the use of trailers and semitrailers. Adherence to specified limitations on fuels and the meeting of transport requirements this year require a comprehensive approach. The construction industry will achieve the planned increase in construction capacities during the Seventh Five-Year Plan with the current level of fuels, and accordingly even this year it is necessary to create the technical and economic conditions for this accomplishment.

Transport tonnage and transport output in ton-kilometers for earth are increasing more rapidly than the amount of construction work. During the Fifth Five-Year Plan, tonnage of earth transported increased by 159 percent, while the number of ton-kilometers increased by 174.6 percent, compared with an increase of 150.4 percent in the amount of construction work; during the Sixth Five-Year Plan tonnage increased by 162.9 percent, and the number of ton-kilometers by 180 percent, compared with an

*tkm = ton-kilometers

increase of 127.4 percent in construction work. During the last 10 years, the indicator of tonnage per million korunas of construction work has increased by about 17 percent, and transport output in ton-kilometers has increased by about 64 percent in the same period; transport distance has increased from 2.6 kilometers in 1970 to 3.7 kilometers in 1979 and is still on the way up.

/The intensity of demand for earth transport is reaching a level which exceeds the real capabilities of not only plant but also public motor transport, and is becoming the limiting factor for smooth progress in construction. Under current conditions, the demand must be met within the specified limitations on fuels. Accordingly it will be necessary to employ nontraditional solutions. Limited tests on construction projects indicate that the planned amounts of earth-moving work are frequently excessive and should be limited; otherwise there will be a decrease in the utility value of construction work. In addition, the dumps of humus and earth that have been set up are far too distant and do not make use of possibilities near the construction sites./

In its decree on the 1980 plan, the CSSR Government ordered the central organs managing investor and contractor organizations to minimize, even in preproduction investment preparation, the amount of excavation and filling, to decrease earth haulage distances and to limit secondary working and hauling.

On the basis of this decree, a statewide test and review of the scale and advantageousness of excavation, filling and haulage of earth is being carried out in order to limit them substantially and decrease haulage distances; this applies to:

/--all projects worth more than Kcs 2 million FN either uncompleted or planned for commencement this year;

--line projects with earth-moving work amounting to more than 10,000 cubic meters;

--other projects with earth-moving work amounting to more than 5,000 cubic meters./

This by no means implies that other projects should remain outside the sphere of interest of either contractors or investors.

The special-purpose inspection commission, consisting of representatives of the general designer, the investor and the construction contractor, will check the following in accordance with the nature of the project:

/--selection of a construction site in terms of the use of local filling materials;

--line projects and fill-type dams in terms of minimizing haulage distances, haulage of earth, use of the nearest supplies of filling materials, and possible new solutions;

--landscape improvements in terms of not entailing the hauling of soil further than 5 km from the edge of the work area and in terms of the benefits to accrue from the proposed improvements and of the amount specified;

--foundation construction in terms of use of progressive methods with limited earth work;

--trenches and pits in terms of the benefits of the earth-moving work and minimization of the quantity, while adhering to the regulations of state standards./

The inspection commissions have a financial interest in achieving savings, and the construction organizations will have their planned output decreased in accordance with their success in limiting earth work, even with lower budget expenditures on the projects.

By its scope and its approach, this inspection lays the groundwork for new methods of working out the relationship between demand and supply. The experience obtained will be used fully in the draft plan for 1981 and the Seventh Five-Year Plan. This one-time project will handle the conflict between transport supply and demand in a nontraditional way, and within the plan for 1980 it will test the starting basis for the Seventh Five-Year Plan. It must be approached from this viewpoint and must be given the requisite support at all levels.

Essentially there are two ways of accomplishing the material tasks of the construction industry designated by the state plan in the context of the limitation on motor fuel, namely thrift in consumption and a decrease in the amount of transport and in haulage distances. An analysis of the connection between the construction industry and transport has indicated new potential for solving the problem.

Another area in which it is necessary to look for ways of decreasing the energy intensiveness of the construction industry is a decrease in the consumption of energy-intensive materials and products based on petroleum products. In the forefront is the consumption of cement, even though currently supply and demand are in balance and cement output fully covers production requirements and market supplies.

/Cement consumption, should, however, be approached in terms of its demands on the fuel and power reserves of the national economy. This justifies the requirements for conservation of cement and for examining the current level of consumption both in carrying out construction projects and in preproduction investment preparation, where the question

is in particular the thriftiness of the construction work and of the proposed design itself./

The problems of decreasing cement consumption cannot be put off until after 1980, because the intensity of cement demand in construction during the Seventh Five-Year Plan will be determined by design planning done this year. From this viewpoint, the task is a pressing one, and extensive initiatives should be developed in this direction. Programmatic approaches must be embodied in a unified technical policy of the construction industry. Its basic criterion must be efficiency and decreased energy intensity of construction projects.

The absolute level of cement consumption in the national economy is increasing, while the ratio of consumption to quantity of construction work by contractor organizations is decreasing, as shown by the table:

	1970	1975	1980	Indices $\frac{1975}{1970}$	Indices $\frac{1980}{1975}$
Total cement consumption in the national economy, million tons	7.6	9.8	10.9	128.9	111.2
Use in production	6.5	8.3	9.4	127.7	113.3
Market supplies	1.1	1.5	1.5	136.4	100.0
Production use (tons) per million korunas of construction work by construction organizations	147.5	125.4	110.3	85.0	87.9

Even though cement consumption is gradually decreasing, the Czechoslovak construction industry is one of the most cement-intensive in the world in terms of consumption per inhabitant. The planned consumption for 1980 is the upper limit, and further consumption must contribute to an improvement of the national economy's fuel and energy balance. A decrease of about 1 percent in cement consumption represents a saving of about 12 million kilowatt-hours of electrical energy and about 15,000 tons of fuel oils.

The construction industry is faced with an especially demanding task as regards increasing the insulating quality of external facing wall components in accordance with CSN [state standard] 73 0540. This involves especially facing panels for building, which as a result of building design, have a substantial effect on insulating quality. Current design of reinforced concrete facing panels is oriented toward heat insulation with polystyrene and to the production of so-called "light prefabrication" components.

In connection with the guidance of technical solutions for projects in the Seventh Five-Year Plan toward decreased consumption of metals,

particularly aluminum, and products and components which are highly demanding as regards consumption of petroleum products and other energy and investment-intensive materials, primarily metal-plastic components, the primary method of increasing the insulating quality of facing panels is the use of the domestic raw and other materials base, particularly silicates. The preconditions for this must be created by further utilization of foamed concrete, whose production has been introduced in the republic, and the conditions for whose expansion are in existence. This is a technically demanding task requiring elimination of previous shortcomings and in particular a transition to large-dimension components which will decrease labor consumption in on-site installation.

Even though the new norm will go into force in 1983, even in 1980 it will be necessary to fulfill consistently the tasks associated with changes in facing panels and to find ways to shorten the established time schedules.

Performance of the planned tasks in 1980 and overall effectiveness of construction depend on, in addition to the areas already mentioned, the utilization of machine capital assets, and the performance of their own capital construction by construction enterprises in accordance with the tasks of structural development in the Seventh Five-Year Plan.

The planned increase in capital assets will make possible the development of construction capacities provided that the tasks regarding their time and output utilization are fulfilled and the dispersion of equipment on projects is decreased by concentrating it on the decisive investment programs.

From the national economic level it is possible to characterize the increase of machine capital assets in relation to these tasks by their effectiveness and the ratio of labor productivity to worker availability, which is developing as follows:

				Indices		
	1970	1975	1980	1975/1970	1980/1975	1980/1979
Labor productivity, thousand Kcs	96.2	130.4	166.6	135.6	127.8	104.8
Effectiveness of machinery capital assets	3.58	3.38	2.79	94.4	82.5	95.5
Worker availability (SZP)	26,885	38,596	59,694	143.6	154.7	109.8

/The increase in worker availability is surpassing the rate of growth of labor productivity, which manifests itself on the other hand in a decreasing effectiveness of machine capital assets. In connection with the preparation of the Seventh Five-Year Plan and with limited investment resources, it will be necessary to slow this decrease even this year.

An increase in the effectiveness of machine capital assets is one of the main tasks of the construction industry, which in addition to increasing their utilization is related to the concentration of construction capacities in order to decrease the amount of uncompleted construction, and is affected by the efficiency of development of by-products by construction enterprises. The low level of elimination of obsolete equipment included in capital assets ties the workers to outmoded equipment with a high consumption of fuel./

A decrease in the amount of uncompleted construction would make it possible for the construction industry to eliminate more obsolete and unsatisfactory machinery. While a low level of elimination expands the machinery inventory and increases the level of capital assets in terms of purchase prices, still it decreases efficiency and to some degree covers up shortcomings in organizational and management work. The current approach makes it necessary for the plan to specify priority tasks regarding equipment elimination, and when these are not adhered to, investment resources are decreased to this extent.

With regard to the plan and this breakdown of construction machinery, there is a specific way of increasing their effectiveness in improving time and output utilization, which are increasing continuously. The trend in time utilization of the main construction machines is given in the table (in terms of number of hours worked per machine):

	1970	1975	1976	1977	1978	Indices $\frac{1975}{1970}$	Indices $\frac{1978}{1975}$
Power shovels	1,715	1,714	1,771	1,796	1,879	99.9	109.6
Scrapers	-	1,257	1,347	1,505	1,435	-	114.2
Bulldozers	1,768	1,809	1,808	1,819	1,869	102.3	103.3
Graders	-	1,040	1,073	1,123	1,113	-	107.0
Cranes	1,986	1,883	1,913	1,980	1,967	94.8	104.5

Overall, time utilization of machinery during the Sixth Five-Year Plan is going up; between 1975 and 1976 it increased by 2.7 percent, between 1976 and 1977 by 3.9 percent, and between 1977 and 1978 by 4.9 percent.

Although this indicator comprises the time during which the machine is engaged in productive work (excluding losses or the time required for preparing the machine or maintaining it after work), this represents use of about 75 percent of the annual number of hours in single-shift operation. Thus the task becomes that of increasing machine utilization in multishift operation, which is also one of the ways of decreasing the demand for construction machinery and equipment.

/The production utilization of machinery is constantly at a low level, and while it it increasing, there is still great untapped potential.

Accordingly the measures adopted by the management organs which create the conditions for higher utilization of construction machinery must be consistently observed. Better utilization of construction machinery is not only a task of the construction industry itself, but must also be assisted by machine producers and suppliers. This involves particularly completing sets of machinery and adding to the machine inventory an assortment which is necessary for structural development of construction capacities./

In this connection, the state plan assigns the machine-building departments overall limits on deliveries, which are made specific in discussions of supplier-purchaser relations. Long-term conflicts between construction industry needs and deliveries have made it necessary to balance key construction machinery at the state plan level and also at the department level. This will improve the specificity of material support of the construction industry.

The plan for 1980 assigns the construction industry demanding tasks whose fulfillment is essential to the fulfillment of the economic and social plan in the Sixth Five-Year Plan and is the initial base for the Seventh Five-Year Plan. In addition to carrying out the plan for 1980, an inseparable part of work on the draft plan and the Seventh Five-Year Plan is the development of the "Set of Measures for Improving Planned Management of the National Economy after 1980."

ASSIGNMENTS, TRANSFERS, BIOGRAPHICAL DATA ON FOREIGN CORRESPONDENTS PUBLISHED

Budapest MAGYARORSZAG in Hungarian 27 Jul 80 p 2

[Text] At the right of the page MAGYARORSZAG's readers can find a list of the names of MTI correspondents who regularly contribute information and articles to this paper from their places of assignment. From time to time this list changes. Some return home at the end of their assignments, there are young newcomers whose names must also be presented, and others are merely being transformed to new assignments. It also happens fairly often that a name will be found that had figured there previously, but had disappeared for a while, because after a number of years here in Hungary the person has once again taken up in some foreign capital.

Dr Miklos Pek, the new MTI correspondent in Sofia, is 29 eyars old. He completed his education at the ELTE [Lorand Eotvos University of Arts and Sciences] in the State and Jurisprudence Department, and after obtaining his diploma immediately went to work in MTI's Foreign Affairs Section. In 1976 he received a certificate from the MUOSZ [National Federation of Hungarian Journalists] School of Journalism. In early 1977 he received a long-term assignment to Moscow, which he covered for the news service for two and a half years. During the time he was in the Soviet Union he had the opportunity to visit more than half a dozen of the republics in the continent-scale country. He told readers about his trips in his stories. He has been back in Hungary since fall of last year, working as column editor of the MTI Foreign Affairs Section. He is not unfamiliar with his new assignment, having substituted for the regular Sofia correspondent in the summer of 1976. In addition to Russian and Bulgarian he works in German and English.

Istvan Kelemen, MTI's new Warsaw correspondent, is 33 years old. He was educated at the ELTE Liberal Arts Department, majoring in Russian and English. After receiving his diploma he began work for Hungarian Radio. From 1971 to 1973 he attended the MUOSZ School of Journalism. Working for the radio was good training for him. Among other things it accustomed him to the deluge of information that floods us these days, to evaluating it and preparing it for dissemination. He was already working as a leading member of the editorial staff for the radio when he transferred for 4 years to another area of press work: The Nation--The World.

There he learned another form of journalism, a freer, more colorful way of presenting information. In February 1979 he began working at the largest institution for foreign affairs journalism in the country, MTI, where he was in the foreign affairs section until his assignment as a correspondent. The Warsaw assignment is familiar to him: during the past 10 years he has frequently been to Poland as a member of delegations of newspaper writers. Most regularly he was there this February when he covered the PZPR congress together with the permanent MTI correspondent there at the time. He knows Russian, English, Polish and German.

There is also to be a change of correspondents in Washington: Andras Heltai is returning to Hungary, being replaced by Pal Bokor. There is no need to introduce Moker since in the past we have frequently been able to publish interesting, analytical writings by this former Moscow correspondent.

To each new correspondent we wish good work and much success!

ENTERPRISES MEETING CHALLENGE OF NEW DEMANDS, REGULATIONS

Success Formula at BRG

Budapest NEPSZABADSAG in Hungarian 23 Aug 80 p 3

[Interview with Sandor Stenczinger, director general of BRG (Budapest Radio Technology Factory), Dezso Karacsony, director of operations and Bela Bodry, party secretary of the factory, by Istvan Oroszi]

[Text] "Navigation is a necessity," said the ancient Romans and they took to the sea to conquer new lands and new markets. This saying is quoted today at enterprises where, in spite of more difficult and complex conditions, there are purposeful initiatives aimed at the discovery and utilization of new opportunities for progress.

One of these enterprises is the Budapest Radio Technology Factory which produces mobile radio telephones, tape recorders and computer devices. How did this medium-size enterprise of our telecommunications industry, with 3,800 employees, succeed in transforming its product structure? What new methods are they using to improve their competitiveness and market position? These are the questions we asked of Sandor Stenczinger, director general of BRG, director of operations Dezso Karacsony and party secretary Bela Bodry.

Our paper was represented by Istvan Oroszi.

[Question] The experience of the first half of 1980 shows that not all enterprises were able to adapt, in a flexible manner, to the new conditions and requirements represented by the new regulators. In fact, some of them are struggling with serious financial difficulties. What is the situation at BRG?

[Stenczinger] We have no reason to complain. This situation has certain historical roots. Near the end of the 1960's we came to the conclusion that BRG was producing too many types of products and spreading its resources too thinly. We found it highly unlikely that we could make sufficient progress over the long haul on such a basis. Thus, if the enterprise wanted to do well, it was necessary to concentrate our forces, reduce our product scale, and accelerate the production of goods that are in line with the conditions

at BRG, can be manufactured economically and can be sold in all markets. We needed also to cut down on the manufacturing of products that cannot be made economically feasible. This strategy proved correct and, to a large extent, it has been implemented. Briefly, this is the reason why the changes in the regulatory system did not find BRG unprepared. The requirement of using competitive world market prices is not as new or unusual for us as it is for others.

[Karacsony] In the past we always sold our products at world market prices and bought the import materials we need at world market prices. We have not received state support; we have not asked for it and do not need it. Therefore, reduction or elimination of support cannot cause us the kind of financial hardship that some other enterprises are experiencing. Concerning the BRG prospects for 1980, let me mention some illustrative statistics: last year the capitalist exports of the enterprise grew by 33 percent. We planned for a further 20 percent growth this year. Our socialist exports, representing more than half of all sales receipts for BRG, will grow at the same dynamic rate as before. Domestic sales of our products will decline, but the total sales receipts of the enterprise will be somewhat greater than last year.

[Question] How much profit do you expect?

[Stenczinger] As a result of regulatory changes, profits will be reduced by half. This decline has a substantial impact on BRG but will not present us with unsolvable problems. The financial position of the enterprise is stable. The BRG's debts are in line with its resources. It can use its own resources to create the funds necessary to repay earlier investment bank loans and to finance ongoing development projects, planned economic growth and a somewhat slower rise in personal incomes.

[Question] I believe there are not too many enterprises that are facing the future with so much self-assurance. In the trade there are those who say that the BRG is a lucky enterprise with a good profile.

[Karacsony] When people talk to me about our lucky profile I always say, pardon the expression, that we did not win our profile at the lottery. BRG has shaped it the way it is today. We mentioned this before. A lot of other enterprises did or could have done the same by making long-range decisions on what to make and what not to make. But I will go further: I do not believe anyone seriously thinks that the progress and profitability of an enterprise is determined by its product profile alone. A profile is "lucky" only if there is purposeful management making steady efforts toward the implementation of an economic product structure, modernizations of products and manufacturing techniques, organization of marketing and many other factors. If these are lacking then an enterprise will fail even with the best profile. The BRG tried once to make a product within our profit and we almost went bankrupt. I am talking about the "super tape deck" as it is still called. The BRG spent millions to develop this entertainment tape deck with the ability to play backwards and forwards. The technical conditions of up-to-date manufacturing were lacking; in addition, the price of the device would have been prohibitive.

[Stenczinger] We were forced to conclude, on the basis of this ill-fated enterprise, that we will never make it or even earn an honest living by making tape recorders, even if we provide a more solid development base. The capacity of the domestic market is too low (80,000 to 100,000 tape recorders annually) to provide a basis for economic production runs while assuring sufficient selection. Considering that, as a result of domestic supply difficulties, the electronic components necessary for manufacturing the device (e.g., transistors) must, in most cases, be procured from capitalist markets, it is clear that under such conditions the BRG could not become competitive in international markets.

This is what caused us to look around in the world and try to see where and how we can aim for competitiveness. We learned that, although there are many manufacturers of complete tape recorders abroad, some subassemblies are produced by a few companies, while others are made by an even smaller circle of manufacturers, in spite of the great demand for them. By proposing to satisfy this demand, the BRG could begin to make new products in great quantities and sell them in both socialist and capitalist markets. After we found international cooperative partners, we decided to make and develop so-called mechanical subassemblies instead of complete tape recorders (e.g., recording heads and motors). This will eliminate the need for imports of mechanical subassemblies. Economical capitalist exports of the same products will provide the funds needed to cover the currency expenses associated with the imports of electronic components that the BRG will continue to require, although our requirements will grow at a slower pace than our production will.

[Question] What is the present status of this large scale product shift?

[Karacsony] Production of tape recorder subassemblies represented a mere 10 percent of the value of the production of our enterprise 5 years ago. It represented 30 percent in 1979, and this year its share will be about 40 percent. We stopped making the old, obsolete reel-to-reel tape machines and replaced them with new, modern cassette units. The enterprise has already earned some profits with these. The production of complete entertainment tape recorders declined from the earlier 60 percent of total BRG production to 10 percent. Had we not developed the production of tape recorder subassemblies, we would have had to spend $3 million on purchasing them just this year. These imports were reduced to $200,000 as a result of the product shift.

[Bodry] Seventy percent of our production of recording heads goes for export. We have cooperation agreements with a number of firms abroad, including one of the big tape recorder manufacturing companies in Western Europe, valid for several years. Our Soviet partner enterprise is shipping color television subassemblies to Hungary in exchange for our tape recorder subassemblies. Assembly line production of tape recorder motors started 1 year ago. The quantity of production this year will approach 500,000 units.

[Question] Where does the BRG find the labor force and production capacity to account for such a dynamic rate of development?

[Stenczinger] As the saying goes, "if your arm is too short, step closer." This led us to an idea to try to offset the shortage of money and labor in a way that is unusual in domestic practice. At home we were also looking for partners able and willing to cooperate with us on an economic basis. This led to agreements, lasting 5 and 10 years respectively, between the BRG and two cooperatives in the provinces to jointly manufacture components and assemblies. The cooperative contributes buildings and labor to the association. We provide machinery, materials and technology. The association with the agricultural cooperative is 2 years old. The one with the artisan cooperative has been in existence for 1 year. Expanding production will not require new construction investment. In fact, the cooperative venture enables the two cooperatives to utilize their existing plants and unused capacities. They are providing full-time employment for hundreds of workers and producing more valuable products than in the past.

[Question] This is indeed a new initiative and the BRG has done it ahead of a lot of other enterprises. Surely another advantage comes from the independent export rights enjoyed by the BRG and the existence of a well-organized in-house research and development department.

[Karacsony] We have enjoyed independent export rights for the past 10 years jointly with other telecommunications industry enterprises within the framework of the Videoton Corporation and the Budavox Corporation Foreign Trade Enterprise. The director general of the BRG is on the boards of both associations. Thus, production and foreign trade are, in practice, concentrated in one hand. This indeed makes it easier to coordinate engineering development and marketing operations. There are, however, occasional debates and conflicts.

[Bodry] People in development often think that sales are none of their business and should be left to the foreign trade specialists. The latter, on the other hand, often expect the people in development to solve marketing problems. Therefore, in agreement with the economic leadership of the BRG, we say that the designer or development specialists should not only design, but also take part in, the initial businesss negotiations. He should be out there in the marketplace to see if the new product is needed and whether it can be sold at a good price.

[Question] In-house research and development is considered a high-risk, but necessary and useful investment, even by the largest capitalist enterprises.

[Stenczinger] We are just a small firm but this also applies to us. Whether a product is up-to-date and economical is decided largely at the development stage. Money must not be withheld from development. More than 50 important, internationally noted inventions have been accepted for use in new, modern products made by BRG. But we pay invention bonuses only to the extent the BRG can recover them in economic terms. Thus, researchers have an incentive to invent things that can be made at BRG and can be sold at a good price.

[Bodry] High risk means, in our case as in others, that in research and development time is money, in a double sense. We found this was so most recently in the development of the BRG tape recorder motors where, in certain

critical periods, almost the entire public opinion of the enterprise had to be mobilized in order to solve complex engineering problems and start assembly line production on schedule. Further success of the product shift was largely dependent on this, as was our accelerated development. Therefore, it was not at all the same for us whether the development of the new product took 3 years or 5 years.

[Karacsony] I would emphasize another important factor in market competitiveness and risk: pricing. Until now, enterprises had a capitalist export plan. As long as they fulfilled it, everything was all right. Today's system of regulators forces us to make sure that the world market competitiveness of a product is recognized in capitalist market prices to a larger extent than before. I will give you an example.

Recently our foreign trade specialists returned from abroad saying that in such and such a place they could sell BRG products much easier if only we would lower the price. In reply we asked to find out what is it that the customer would be willing to pay extra. This is because if we can make the design changes he needs at a cost that is less than the price differential we could get, then this is a good deal for us. Otherwise, we do not need the business. Our foreign trade specialists were taken aback. But then they collected themselves and came to an agreement with the customer, just as we thought. In the end, the deal ended up being three times as big as the one discussed originally. In exchange for the higher price, the BRG undertook to make the modifications requested by the customer; the capitalist firm that competed with us was unwilling to do this.

[Bodry] Of course, the heat begins later, as interests within the factory collide. The changes interfere with the regular work of the factory. The new product requires more attention and is harder to make than the old one. But this is what life is all about. We must get accustomed to the difficulties.

[Question] Some people say the CEMA market does not require such hard work and that it is possible to get by without all this.

[Stenczinger] In CEMA markets we are also meeting the customer halfway. For example, we hold conferences and trade shows in the USSR every year. There, we regularly obtain detailed information from our customers regarding the modifications they would like to see in the BRG products we are shipping to them. Next time, we present our products tailored to their wishes. This is why they recognize us. This is why they are pleased to buy from us and arrive at mutually advantageous, correct business deals.

In any case, the two markets cannot be rigidly contrasted or separated. If BRG products did not have a substantial CEMA market then we would have been unable to use high quality mass production methods. We cannot sell sufficient quantities just to our capitalist partners to make it pay for itself. Economic production and exports can only be based on the combined capacity of the two markets.

[Karacsony] There is competition also in the CEMA market. For example, in the past 7 years two CEMA countries besides ourselves were making so-called report storage tape recorders used in industry and transportation. Since engineering quality rose faster at our factory and economic parameters improved significantly, production stopped everywhere else almost automatically. As a result, today we are the only ones within CEMA who are still making and exporting these special tape recorders, usually produced for individual orders. We might say that CEMA specialization happened in this case without special recommendations, by economic means.

[Question] What has been said thus far provides very interesting and convincing proof that the accomplishments of the BRG are indeed due not to luck, but to local flexibility, effort and adaptability. Therefore, I would like to ask your opinion concerning the outlook and risks for the future.

[Stenczinger] We are continuing the transformation of our product structure in the other major product group of our enterprise: radio telephones. These also contain mechanical components and subassemblies that can be mass-produced at the BRG, provided that, as in the past, marketing can be assured by long-term international agreement.

We have also begun the development of an up-to-date FM radio telephone system, primarily to satisfy increasing demand in developing countries. At customers request we are willing to provide this or similar systems on a principal contractor basis.

[Bodry] The BRG had to pay a substantial entry price to get into the capitalist market. This kind of risk and others similar to it must be reduced by improving operations within the enterprise. For example, just by improving material supplies we could achieve a 10 percent improvement in efficiency. Another great reserve of risk is represented by improved reliability of our products, reducing the number of customer complaints regarding quality. This requires more responsible work and, among other things, good customer service. The latter will be organized first of all in the largest market for BRG products, the USSR.

[Karacsony] Today we are more sensitive to risk than in the past. Therefore, we would like to obtain independent import rights to complement our independent export rights. In the new situation, the BRG may gain or lose millions on the timing and price of the components needed for production, almost one half of which are imported from capitalist countries. This is why we would like to have full autonomy and responsibility also in this area.

Over the Hump at DIGEP

Budapest NEPSZABADGAG in Hungarian 23 Aug 80 p 3

[Interview with Sandor Enekes, director general of DIGEP [Diosgyor Machine Factory], by Attila Gyorgy Kovacs]

[Text] The low point in the history of the Diosgyor Machine Factory, an enterprise with 10,000 employees and a great past, occurred in 1978, the year when the enterprise was reorganized. It is now clear that this event

marked the beginning of progress in the right direction. The revamped leadership mobilized thousands of workers who hoped for renewal but still had their doubts. The results of the first half of this year show a declining workforce producing 19 percent more value than last year; sales receipts increased by 14 percent.

The road is both steep and difficult. In the middle of the long climb one feels how long there is still left to go. Where is the enterprise coming from and where is it going? This was the subject of our conversation with director general Sandor Enekes.

Below the Mark

[Enekes] During the critical year, the financial stability of our enterprise was threatened; we were losing money on production and had underfulfilled our plan. The inquiry at the time of the reorganization showed that our low performance was due to weakenesses in leadership, problems of organization and internal cooperation, and the backwardness of management and technological development. During the Fourth Five-Year Plan the DIGEP was operating on a day-to-day basis, without providing foundations for the future.

Investment and enterprising spirit were in decline; machinery was obsolescent. We were ill prepared for the modernization of our product structure. Enormous inventories indicated that part of our product range is unsaleable. Some unsuccessful efforts were made to fulfill certain international obligations, while the production of goods in high demand declined. This led to a catastrophic 75 percent decline in productivity and the disappearance of development resources.

[Question] How did you find your way out of this difficult situation?

[Answer] In part with the help of our superior organizations, but mainly as a result of our own consistent, unsparing efforts. Briefly: we accelerated the pace of our investment projects; reduced our product scale on the basis of ranking according to profitability; we improved in-house cooperation and regularity of production by introducing a bonus system with more incentives; we replaced one half of our totally depreciated high performance machines (there were 90 of them); through organization, we created the basic conditions necessary for more efficient and disciplined work.

[Question] At what point is the DIGEP today?

[Answer] I have to give you an answer based on three criteria. This shows that we have merely made the first few steps. By improved management and political work we achieved results that are in line with, and in some cases better than, the plan. Nevertheless, our productivity is only 75 percent of the best plants of the Hungarian machine industry and only one-third of the international standard.

[Question] What is the key issue?

[Answer] Per capita production value last year was 320,000 forints. In the first half of 1980 it increased by a quarter. Our goal is to raise this figure above 500,000 in 5 years. The ratio of workers to white collar employees is 100:42. Thus, the key issue is improved efficiency and, in particular, a decisive improvement of productivity.

Discipline and Responsibility

[Question] One hears complaints about an excessively tight rein. A lot of people are questioning, either explicitly or implicitly, how long can you continue the management practices you introduced 2 years ago as "emergency measures?"

[Answer] True, after 2 years I am still directly in charge of the production plants. This is not the task of the director general, some say in reproach. But I repeat: even though production has been consolidated, we have still taken only the very first steps. Day-to-day reporting on each task is burdensome. I think all managers feel ill at ease in the role of a despatcher. There was more than personal whim on my part behind the elimination of our production directorate. It was unable to cooperate normally with other organizations. The fact is that cooperation among the various production units was unbelievably bad; management organization was confusing and plagued with parallel authorities and bureacracy. Responsibility and initiative were lost among the gears of the machinery.

To build a house on solid foundations, we first need to prepare the building site. Along with the day-to-day work of building the foundations we must also carry out the tasks aimed at alleviating our problems over the long haul and serving our future.

[Question] This is true; but you are doing the work of others. When a worker in one of the workshops asks his foreman for extra time above the production norm it is necessary to obtain approval from the director general. Is this not overdoing it a little?

[Answer] For the time being, there is no other way to shed light on problems. I check on the daily plan fulfillment of factory units. If some units are lagging behind, I ask the person responsible the reason. The purpose of the morning conferences in not to get explanations, but to find out what they are doing to eliminate the reasons for the lag. I check on this every day. I do not interfere with the means of execution, but I want to make sure it is clear who has the responsibility. This directly forces each manager to bring himself to a point where he can direct his area in a responsible, well-informed manner.

Let me mention the matter of extra time beyond the production norm. Let us start by assuming that the worker wants to work for 480 minutes every working day. In fact, the amount of time he can work is determined by management, i.e.,

the availability of tools, materials and drawings. Suppose the production norm for a certain item is 2 hours. Material is not always available, so the worker is unable to fulfill his monthly norm. His wages will decline; thus, he has a right to complain to his foreman. They have been working together for a long time, so the foreman will ask for extra time from the norms analyst. Of course, a different reason is given (e.g., wrong size material), even though the real reason was deficient work organization and management. The worker gets his wages; productivity declines; there is no performance behind the money. The point is that there are 20 valid reasons to ask for extra time beyond the norm, and they are all uncontrollable. What are we doing to avoid this kind of collusion? We ask the technologist to record, in a numbered journal, all the data on requests for supplementary norms: who is asking for time and why? They must also name the person responsible. Extra time can only be given in case of a mistake. The person making the request is the one who must know best where the fault lies. The journal comes to me. On a statistical basis, it becomes clear who the managers are in the areas where such manipulations are most frequent. This is taken into consideration at evaluation time and when bonuses are awarded. After a while, those who are involved will pay attention to more regular supplies and workers are not adversely affected.

[Question] Let us change the subject. Many consider the new system of bonuses unjust. Were there occasions where factory units who fulfilled their plan did not receive any bonuses?

[Answer] That is true. I would merely like to add that the new system of incentives was introduced in agreement with the trade union and the party committee. We specified not only the timely and good quality fulfillment of the plan, but also that these prerequisites must be present in the operations of the enterprise as a whole. We are all in the same boat. There is no such thing as a good production unit within an unsuccessful enterprise. In the beginning there were some conflicts. Today, every production unit is interested in the problems of other plants and will not sit idly by while their neighbors are struggling with problems.

In Many Keys

[Question] People are talking about large scale employee transfers in the interests of improving productivity. What is the truth?

[Answer] We formulated a program in this area stretching over several years. The question is how can we increase per capita production, whether we intend to increase the value of production with the same work force, or whether we want to preserve the existing value with a declining work force. Employee transfers are merely one of the methods available. With the help of the workers we made a survey of thousands of jobs to see if there are any duplications and what could or should be done differently. Every year, we transfer 2 to 3 percent of the work force from office jobs to production. The people involved are given three choices, depending on their age, abilities and problems. If none of these is acceptable, they are transferred to discretionary status. This means there are no wage increases or promotions. It is in their interest to get out of this category or to look for a job elsewhere.

This is only one of the sources for the planned 47 percent improvement in productivity. Others are the purchase of high performance machinery and its utilization for at least 2.5 shifts per day. There are great reserves in the area of better utilization of working hours. This year we will be freeing 640,000 norm hours by means of better organization, improved material supplies and norm maintenance. This represents 10 percent of our capacity. The electricity consumption curve of our factory gives a good indication of the presence of such reserves: around 6:30 am the curve rises; around 12:30 pm it starts to decline. If we want to reduce our annual losses, now approximately 45 million forints, we must know that they are due 50 percent to faulty materials, and 50 percent to rejects. On the one hand, we will institute stricter incoming inspection and utilize the abilities of our lawyers; on the other hand, in the area of work quality we can rely on our 800 socialist brigades, the achievements of the DH [Worker Without Mistakes] work system, and the large numbers of innovators we have.

The requirements are changing rapidly and we must adapt to them. It took us 4 years to turn a development result into pilot production. We reduced the number of research projects and called in outside professionals so as to substantially reduce the time needed. We intend to introduce a number of product lines that can last for a long time, by means of license purchases and cooperative projects. Most of our products require constant development and design changes. In cooperation with foreign trade specialists we are developing market operations and we are trying to formulate a suitable system of incentives that encourages profitability. We have already signed a contract with Technoimpex that provides incentives for expanding our market and strengthening our positions.

Our principle is to take market demands into consideration, but to supply only those demands that promise healthy profits, assured sales, efficient work and, in the final analysis, enable us to earn a secure living.

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

THIRTY-TWO YEARS OF BULGARIAN-SOVIET TRADE REVIEWED

Sofia OTECHESTVEN FRONT in Bulgarian 18 Mar 80 pp 1,3

[Conversation with Valentin Aleksandrovich Dyakov, trade representative of the Soviet Union in Bulgaria: "Our Country Has Never Had a More Loyal Ally"]

[Text] "This treaty fully meets the vital interests of our people, reflecting its most profound aspirations. The implementation of this treaty will give our people even greater confidence in the justice of their cause and will double their creative efforts in the building of the Bulgarian People's Republic."

This historic statement was made by Georgi Dimitrov, 32 years ago, on 18 March 1948, at the Big Kremlin Palace, at the signing of the Friendship, Cooperation and Mutual Aid Treaty between the Bulgarian People's Republic and the Union of Soviet Socialist Republics.

The conclusion of this treaty was a historical event not only in relations between our two countries. It marked the beginning of a new stage in the development of Bulgaria and in the strengthening of its national independence and sovereignty. The treaty is the first equitable political document concluded by our country. It laid solid foundations for its development along the path of socialism and helped to establish Bulgaria in the international arena.

The 32 years which have passed since convincingly confirm the strength and vitality of the treaty. It became the starting point for the strengthening and intensification of Bulgarian-Soviet friendship and the development of Bulgarian-Soviet relations in all fields of life.

On this occasion, we chose the USSR Trade Mission as the spot for our article. Inside its new beautiful building we were hospitably welcomed by Valentin Aleksandrovich Dyakov, trade representative of the Soviet Union, who shared with us a few thoughts on the headlong development of economic relations between the two fraternal countries.

The chronicles of Bulgarian-Soviet economic and trade relations began precisely three years before the Friendship, Cooperation and Mutual Aid Treaty was concluded. On 14 March 1945, while World War II was still raging and the Soviet people were fighting for the liberation of the European nations from Hitlerite fascist oppression, the first trade agreement was concluded between the USSR and the Bulgarian People's Republic. This was the first postwar treaty concluded with a country belonging to the just-created comity.

In order to be more convincing, allow me to mention merely a few figures which clearly depict the development of our cooperation. Whereas in 1945 the USSR exported to Bulgaria 73,000 tons of petroleum and petroleum products, in 1980 such exports will total 13 million tons of petroleum and two million tons of petroleum products. In 1945 Bulgaria imported 16,000 tons of ferrous and nonferrous metals. This year such imports will exceed three million tons. At that time Bulgaria received from our country 2,000 tons of cotton. Current cotton imports total 40,000 tons.

Here is another interesting and significant fact: in 1945 Bulgaria received from the Soviet Union agricultural equipment totaling 10 combines and several dozen tractors. Today, on the basis of the cooperated deliveries system, we purchase from Bulgaria agricultural equipment worth 140 million rubles.

Whereas in 1945 trade between the two countries totaled 120.6 million rubles, today it has increased by a factor of 55. In other words, in one week we are trading the same amount of goods we traded in the entire year of 1946.

Mikhail Mikhaylovich Korolev, head of the economic department of the trade mission, joined in the conversation:

"Compared with 1948, our trade has increased by a factor of nearly 50. At that time it totaled 150 million rubles. This year it will reach 6.6 billion rubles."

The figures mentioned by Comrades Dyakov and Korolev are eloquent. They are a factual expression of the parameters of our friendship. Only a few days ago Petur Mladenov, member of the BCP Central Committee Politburo and Minister of Foreign Affairs of the Bulgarian People's Republic stated in an article in IZVESTIYA that, "cooperation with the Soviet Union became the main foreign political factor which enabled the Bulgarian state to assume leading positions in the building of mature socialism and in strengthening its international prestige."

I asked Comrade Dyakov to describe the way the structure of trade between our countries had changed over the years.

"Until 1960 Bulgaria was virtually not exporting machines and equipment. It was exporting agricultural raw materials and products only. Subsequently, particularly over the past 15 years, with the help of the Soviet Union a developed industry was created, to the point that Bulgaria is exporting to our country equipment worth one billion 560 million rubles and the USSR imports complete machines and equipment worth 800 million rubles. What better description could be given of the increased possibilities of the Bulgarian economy?"

"Allow me also to emphasize," Comrade Korolev added, "that all agricultural commodities exported by Bulgaria to the Soviet Union are processed, since this is a more effective method. The same applies to consumer goods such as clothing, knitwear, shoes, cosmetics, and pharmaceuticals.

"The USSR is a stable market for Bulgarian commodities, insuring employment and economic stability," Valentin Aleksandrovich went on to say. "Over 55 percent of Bulgaria's trade is with the Soviet Union. In 1979 it equaled the sum total of trade between 1956 and 1960 and 1961-1965 together. In the Seventh Five-Year Plan the level reached over the three preceding years will be outstripped and trade will total 28 billion rubles.

"Our trade and economic relations reciprocally supplement the national economies of the two countries. As trade develops the share of reciprocal deliveries of machines and equipment rises considerably; 38 percent of them are based on specialization and cooperation. A number of examples may be cited in this respect. Let me merely mention the fact that in the city of Toliatti, one out of two Zhiguli or Lada cars is equipped with parts produced in Bulgaria."

Gradually, our conversation turned to the present, which marks the implementation of the plans considered in the first treaty. In order to illustrate his thoughts, Comrade Dyakov used an interesting example which shows the scale of the changes in the trade between the two countries.

"If we consider the sum total of USSR supplies to Bulgaria as equaling 100, 70 percent of that would be raw materials and only 30 percent would be finished goods. Thus, for example, your country received 6.3 million tons of power industry and coking coal, 4.3 billion cubic meters of natural gas, fertilizers, cotton, cellulose, and paper.

"The principle of the process of further intensification of the development of economic relations, and the rapprochement between the economies of the two countries and the development and intensification of integration processes and cooperated deliveries has been included in the general plan for specialization and cooperation in the field of material production adopted by Bulgaria and the Soviet Union, which will run until 1990. This plan

was formulated with the participation and direct guidance of our party and state leaders, Comrades Leonid Brezhnev and Todor Zhivkov."

Economic cooperation and integration between Bulgaria and the Soviet Union, this powerful booster in the development of our country as a modern industrial-agrarian state, has faced the development of Bulgarian-Soviet relations with new strict requirements.

In this connection, and with a view to the further all-round rapprochement between our two countries, on 12 May 1967 a new Friendship, Cooperation, and Mutual Aid Treaty was signed by Comrades Todor Zhivkov and Leonid Brezhnev.

This treaty became the logical extension of the 1948 treaty and of the further blossoming and enrichment of its ideals and principles.

In conclusion, my collocutors cited yet another example which, in my view, eloquently shows the growth and development of our relations. Whereas in 1945 freight hauled from the Soviet Union to Bulgaria totaled 210,000 tons, while freight in the opposite direction totaled 15,000 tons, today it has reached 35 million tons. In terms of freight cars, the length of such a train would be 32 kilometers.

Thirty-two years are a sufficient period of time to be used as a convincing proof of the lasting ties and feelings which link our two fraternal peoples led by consistent communist parties marching shoulder to shoulder under the pure victorious Marxist-Leninist banner to the bright horizons of socialism and communism.

Leaving Moscow after the signing of the Friendship, Cooperation and Mutual Aid Treaty, 32 years ago, Georgi Dimitrov, our immortal leader and teacher, said the following in his speech at the airport:

"I know the Bulgarian people well and I can assure the Soviet brothers that they will remain their friend loyal to the end, whatever may happen in the future. The Bulgarian people will never betray their elder brother-liberator."

Thirty-two years later, expressing the thoughts and feelings stemming deep from the hearts of all Bulgarian citizens, in his speech at the National Conference of the Fatherland Front, Comrade Todor Zhivkov said:

"Our country has never had a more loyal, more selfless, more sincere and more staunch ally than the Soviet Union; it has never been so free, so independent, and so confident of its present and future...."

DEVELOPMENTS IN SUGAR BEET TECHNOLOGY PROMISE GOOD CROP

Sofia KOOPERATIVNO SELO in Bulgarian 23 Aug 80 p 1

[Article by Nikola Kutrev, director of Sugar Beet Production of the Bulgarian Sugar PAO [Industrial-Agrarian Trust]: "Using Our Experience"]

[Text] We are on the eve of one of the most difficult agricultural campaigns--the sugar beet harvest. This year the APK [Agroindustrial Complexes] and the PAK [Industrial-Agrarian Complexes] devoted a great deal of effort to prepare the soil and plant and raise the crop. A major step forward was taken in the application of the scientific technology developed by the Sugar Beet National Industrial Complex near Shumen, expanded with the positive practical experience of the producers.

For the first time there was a mass conversion to sowing using a reduced number of seeds. This made it possible to thin the crop more easily and qualitatively. Consequently, today we have the best organized crops in the last five to eight years. Particularly good results were achieved by beet growers in Veliko Turnovo, Ruse, Pleven, Burgas, Stara Zagora and Sliven okrugs. Compared with its previous results, however, Vratsa Okrug achieved its biggest progress! Herbicides were used in a greater quantity and more efficiently. The struggle against main diseases and pests was waged with great precision and promptness. The July and August droughts hindered the development of the plants, particularly in nonirrigated areas. Their condition improved rapidly after the rains. Favorable conditions were created for the intensive growth of root crops and the accumulation of saccharose.

Some ten days are left before the most important and responsible measure within the technological cycle must be undertaken: the harvesting of the sugar beets. A great deal of work must be done under varying and difficult weather conditions. Success in this area depends, above all, on good organization and advance preparations. What has been accomplished so far by the farmers in the APK and PAK, and the collectives of automotive transport enterprises and sugar refineries?

Machine repairs in the plants have been completed. Currently a commission of specialists is conducting a final investigation of all assemblies and

parts with the help of operational and mechanical tests under conditions similar to those in which they will be operating.

The results of the investigations indicate that the plants are ready for the campaign. The capacity of reception facilities has been expanded almost everywhere. The new plant in Kameno, Burgas Okrug, will begin operations at triple its original capacity.

Several days ago the managements of the Bulgarian Sugar PAO, Automotive Transportation DSO [State Economic Trust] and Bulgarian State Railroads DSO reviewed all programs related to the loading and hauling of sugar beets. The number of needed trucks was determined. It was decided that each automotive transportation enterprise and sugar refinery will conclude a socialist competition contract. Such a contract was signed between the Bulgarian Sugar PAO and Automotive Transportation DSO.

The APK and PAK farmers are also intensively preparing themselves for the rhythmical extraction of the beets without losses. All enterprises have adequate KS-6 and Erio model combines. The most important thing is for this highly productive equipment to be used to its full capacity. In order for this to be achieved, the machines must be looked over in the next few days. Only thus will it be possible to avoid unnecessary tension, work rhythmically, and fulfill daily schedules. Spare parts are available at the central warehouse in Gorna Oryakhovitsa. However, the Agromashinaimpeks VTO [Foreign Trade Trust] should supply all the necessary spare parts for the Erio combines. The second major problem which must be resolved as soon as possible is to determine the composition of the mechanized detachments. The APK and PAK have mechanizers with great practical experience. Unfortunately, frequently the machines are assigned to people lacking the necessary training. Also, a number of mechanizers claim that the quality of the equipment is poor. In reality, such people are simply unable to tune properly the operational parts. Beets are wasted and the farms and the state suffer losses. Currently, experienced Soviet specialists are teaching refresher courses in the okrugs, very useful to all.

The APK and PAK have adequate practical experience in the use of material incentives. An example in this respect is the approach of the complexes in Dolna Mitropoliya, Ruse and Kameno. This year again the mechanized detachment will be the basic organizational form. Its advantages are numerous: easier maintenance of the equipment and better facilities for the men, and an easier way for managers to supervise the work process. Naturally, this is only one side of the problem. In order for the work to be fast and of good quality, the automotive combines and sugar refineries must develop a good organization, for everyone knows that by remaining in the field a single additional day, the root crops lose 0.15 percent of their weight and their quality is worsened.

Despite the adverse weather, the crop appears to be good. However, we must not forget that the vegetation period is not over yet. The threat presented

by the noctuid moths and the leaf spot disease is not over. Observations must be continued and, wherever necessary, the crops must be sprayed. Along with the harvesting, we must prepare for the next sowing: the areas to be planted in beets must be indexed. Soil samples must be taken and the soils must be fertilized and prepared. The good farmer thinks of everything in advance!

CSSR TRADE COOPERATION WITH WEST VIEWED

Duesseldorf HANDELSBLATT in German 8/9 Aug 80 p 9

[Article by cmk: "New Search for Western Cooperation"]

> [Text] Prague-Berlin--Even though 30 percent of Czechoslovak machinery exports are still going to Western countries, the export structure must be changed. The reason: In fields where the CSSR used to be the world leader, such as with certain textile machines, it now faces oversupplied markets in the Western industrial states. This is the word from Prague's Ministry for General Engineering.

The FRG is still considered the classical trade partner for CSSR machine manufacture, accepting primarily machine tools and dies, textile machines, passenger cars and tractors. This listing alone indicates that the sphere of interest of the General Engineering Ministry is awesome; according to its own words it stretches from thumbtacks to shipbuilding.

The ministry is responsible for a total of 70 percent of the production of consumer goods for the domestic market. Since both the demand and the purchasing power of the Czechoslovak population are great--the ever-expanding "dacha-movement" has reached a point where 50 percent of the families own two households--the new five-year-plan (1981-1985) is to concentrate on the improved supply of the domestic market, especially with household appliances, bicycles and baby carriages.

The ministry repeatedly emphasizes that in the next 5 years, only certain sectors are to be favored. Of primary importance--especially with an eye to the export capability--are to be the development of energy- and material-conservation technologies in machine tool construction. A higher degree of automation as well as an increased use of electronic control mechanisms are to be of primary interest.

A further favorite topic will be production cooperation, especially since the CSSR has been very modest in this field over the years. According to the Ministry for General Engineering, there are currently only 15 cooperation agreements in force with the FRG, although these agreements are extensive in terms of economic volume. Some 30 cooperation agreements, primarily in the field of machine-tool construction, are said to be in the negotiating stage.

The Czechoslovak planners see the agreements as concentrating on the licensing of production, exchanges of components and joint action on third markets. Prague complains that Western firms often talk cooperation, but actually think only about increasing their own exports.

A great interest exists in the field of automobile construction for cooperation with Western countries. However, there is no wish to follow the Romanian, Polish, or even the Soviet example of constructing an entire production line with Western know-how; rather, the aim is limited to the acquisition of partial licenses (see HANDELSBLATT, 7 August 1980).

The Prague ministry argues that the Czechoslovak automobile industry has a grand tradition and has possessed since 1964 technologies on a European level which are valid even today. All further efforts are to concentrate merely on energy savings.

Licensing negotiations are currently under way with several major Western automobile concerns, including the Volkswagon Works in Wolfsburg, stated the ministry. The conversations are to clarify the possibilities for cooperation in the manufacture of passenger cars. However, the Wolfsburg offers are said to have been not as favorable as those of other West European automakers, and Prague had gained the impression that VW did not have a real interest in passenger car cooperation. According to reports, the discussions centered on a possible collaboration in engine construction.

The General Engineering Ministry commented guardedly on cooperation with the GDR in automobile manufacturing. It could only be learned that the long-term investment contracts are to be restructured and that the number of reciprocal component delieveries has been reduced. Designs for the 1981-1985 Five-year Plan indicate that the CSSR is also thinking about closer cooperation with Western countries in truck manufacturing; negotiations are said to be under way not only with the FRG but also other states. However, the time is not yet ripe to talk about the extent of the consultations, stresses Prague. A hint at the direction of these talks are taking was merely provided by the remark that the Tatra chassis is eminently suited to carry construction machinery.

The basic concept of the CSSR Ministry for General Engineering seems to be that the question of the components of both passenger-car as well as truck manufacture is so extensive that the problem of international cooperation has to be taken very seriously, considering especially that the Czechoslovak automobile Industry has always bought licenses and wishes to do so in the future as well.

CAPITAL ASSET DEPRECIATION SCHEDULES ANNOUNCED

Prague SBIRKA ZAKONU CSSR in Czech No 94, 8 Aug 80 pp 419-426

[Text] Decree of the Federal Finance Ministry, dated 17 June 1980, concerning the depreciation of capital assets.

The Federal Finance Ministry, in agreement with the finance ministries of the Czech Socialist Republic and the Slovak Socialist Republic, in accordance with section 391, paragraph 1 of the commercial code number 109/1964 of the Laws of the Czechoslovak Socialist Republic, and in the sense decreed in number 37/1971 of the Laws of the Czechoslovak Socialist Republic, establishes:

Section 1: The Object and Extent of Modification

This decree modifies the depreciation of capital assets, and establishes the depreciation schedules included in the supplement to this decree.

Section2: Responsibility for Depreciation

1. These organizations depreciate capital assets:[1]

a. State economic organizations; within concerns, concern enterprises and specialized concern organizations depreciate in the same fashion,

b. cultural and educational support organizations,

c. united agricultural cooperatives, communal agricultural enterprises, and improvement cooperatives,

d. foreign trade organizations, with the exception of cooperative foreign trade enterprises,

e. enterprises and the operating equipment of social organizations, as well as the organizational elements of social organizations designated by their central agency, as long as these elements continually perform economic activity, and register separately the capital assets for this activity,

f. other socialist organizations, insofar as decreed by the relevant finance ministry.

2. The depreciation of capital assets of cooperative organizations not included in paragraph 1, letter c, are governed by this decree if established by their central agency; the relevant central agency of cooperative organizations, in agreement with the relevant finance ministry, will decide on case by case deviations in the depreciation of capital assets by these organizations.

3. Capital assets are depreciated by the organization which administers or owns them, or by the concern enterprise (or specialized concern organization) which carries out their administration. Capital assets which have been committed to permanent utilization,[2] or to long term utilization[3] are depreciated, however, by the permanent or long-term user.

Section 3: Method of Depreciation

1. Capital assets are depreciated from the purchase cost[4] according to binding depreciation schedules established in the supplement to this decree, without suspension and up to the amount of the purchase cost.

2. Should an obligation arise to depreciate capital assets which had previously not been tied to such an obligation, then the capital assets are depreciated from the purchase cost, but only to the amount of the current value.

3. In the event of a change in the purchase price, capital assets are depreciated from the changed purchase price, but from the beginning of the month immediately following the beginning of the validity of the purchase price change.

4. Capital assets are depreciated according to their placement in the fields of the individual classification of capital assets established by special regulation,[5] in the case when capital assets are placed in the fields of classes 3 to 7 and the relevant fields are not included in the supplement to this decree, they are depreciated according to a binding yearly depreciation schedule of 12 percent.

5. The current value of a capital asset is understood to be the difference between its purchase cost and adjustments[4] as of the end of the month for which the current value is determined.

Section 4: The Beginning and End of Depreciation

1. Captial assets are depreciated from the beginning of the month which directly follows their entry into the capital asset account,[6] to the end of the month in which their purchase price is completely written off, until further notice; when the onset of utilization of capital assets is earlier, they are depreciated from the beginning o the month which immediately follows their introduction into utilization.

2. Capital assets which are not fully depreciated are no longer depreciated by an organization at the end of a month in which

a. they are placed in mothballs[1] or stockpiled,

b. they are transferred to the control or ownership of another organization,

c. they are assumed for sale by an organization which takes care of performing brokerage services,

d. they are committed to permanent or long-term utilization,

e. the right to their permanent or long-term utilization expires,

f. their physical liquidation commences,

g. they are taken out of service due to damage or defects.[7]

3. In cases where state organizations are obliged to decide concerning the surplus character or uselessness of national property,[8] capital assets which are not fully depeciated may cease being depreciated only on the basis of this decision.

Section 5: Disposition of Current Values of Capital Assets

1. In a case in which capital assets are not fully depreciated and are eliminated as a result of physical liquidation, damages, or defects, an organization accumulates their current values in its costs.

2. In a valid transfer of control or ownership of capital assets, the transferring organization modifies its costs by the difference between their sales price and current value.

3. An organization is required to express completely, and in a timely manner in its financial plan the total of the current value of capital assets planned for physical liquidation into costs.

Section 6: Capital Assets Not Covered by Depreciation

The requirement to depreciate does not extend to:

a. mothballed capital assets,[1]

b. capital assets exclusively designated for civil defense purposes and for special tasks, as long as they are handled as independent inventory objects,

c. real estate,

d. stands of timber,

e. growths of hops and grapes, as well as fruit trees and bushes which have not reached bearing age, or the numbers of which have not exceeded the established boundary of a husbandry unit,[9]

f. facilities for flood control and forestry-technical improvement,

g. other improvement projects up to 2 years following their completion,

h. recreational facilities of organizations stationed abroad.[10]

Section 7: Exceptions

The Federal Finance Ministry may, at the request of a federal agency, grant a waiver from the provisions of paragraphs 2,3,5, and 6 for organizations which it manages, or modify the binding yearly depreciation schedule (hereafter simply "waiver from depreciation"), especially in cases where the capital assets are:

a. constantly, for the whole period of utilization, exposed to extraordinary environmental influences or operational conditions,

b. used in a targeted manner, for the completion of a single delivery, operation, or task, and which become upon this completion superfluous or useless.

2. A waiver from depreciation may be permitted particularly under the conditions that:

a. it is not a matter of constructional, design, technological, functional, and other shortcomings and defects in the capital assets,

b. the capital assets are used, maintained, repaired, and protected from environmental influences in accordance with legal regulations, technical norms, and the instructions of the producer or importer.

3. A waiver from depreciation may only be permitted with a validity beginning on 1 January of the following year when the application for waiver from depreciation was submitted to the Federal Finance Ministry by 1 July of the current year at the latest. An application for waiver must be properly justified and documented in accordance with paragraphs 1 and 2, and must also express the results of the applied for measures according to special regulations.[11]

4. The finance ministries of the republics may, analagously, permit a waiver from depreciation according to paragraphs 1,2, and 3 for organizations managed by agencies of the republics, national committees, and agricultural administrations; as long as it is not a matter of an organization managed by national committees, the finance ministries of the republics may proceed in these matters in agreement with the Federal Finance Ministry.

Section 8: Annulling and Transitional Regulations

1. Decree number 76/1966 of the Laws of Czechoslovak Socialist Republic concerning the depreciation of capital assets is revoked, in the sense of decrees number 103/1970 and 97/1976 of the Laws of the CSSR.

2. Insofar as waivers have been permitted under the revoked decrees, they retain their validity until 1 January 1982; high-level central agencies may, however, after verification of the justification for the existing waivers under Section 7 of this decree, request the relevant finance ministry to arrange for their renewed negotiation and authorization.

Section 9

This decree becomes effective as of 1 January 1981.

Minister: Engr Ler, Candidate for Doctor of Science (signature)

Depreciation Schedules

Field Code[5]	Short Field Name	Binding Yearly Depreciation Schedule (percent)	Orientation Period for Depreciation (years)
	Class 1. Buildings (including accessories)		
801	Buildings of Public Investment	1.3	77
802	Halls of Public Investment	1.3	77
803	Buildings for Habitation	1.3	77
811	Halls for Production and Services	2.0	50
812	Buildings for Production and Services	2.0	50
	In field 812, buildings for		
	--fuel and ore extraction	2.5	40
	--energy generation	4.0	25
	--water management	1.5	67
	--transport and communication	1.3	77
	--warehousing	1.5	67
	In class 1, buildings which are		
	--of wood and like materials	4.0	25
	--temporary[12]	10.0	10

Code[5]	Name	Depreciation Schedule (percent)	Orientation Period (years)
	Class 2. Structures (including Distribution Structures)		
813	Towers, Poles, Chimneys	3.3	30
814	Surface tanks, cisterns, containers, pits	1.5	67
	In field 814, cleaners for waste industrial water	4.0	25
815	Special surface facilities	2.0	50
821	Bridges	1.3	77
822	Surface communication and airports	1.3	77
823	Tracks and area upkeep	1.3	77
824	Track beds	1.0	100
	In field 824, rail superstructure	3.3	30
825	Underground facilities (except mines)	1.3	77
	In field 825, tunnels	1.0	100
826	Underground mining facilities	2.5	40
	In field 826, temporary shafts	20.0	5
827	Long distance and connecting pipelines	1.3	77
	In field 827		
	--water mains	1.5	67
	--cement pipe sewers	5.0	20
	--steam, heat, oil, gas and air pipelines	3.3	30
	--communications cable lines	5.0	20
	--other cable lines	3.3	30
828	Electric and overhead wires	3.3	30
831	Water treatment	2.5	40
832	Dams and waterway facilities	1.0	100
833	Waterway reservoirs, waterway and canal improvements	2.0	50
	Temporary class 2 structures[12]	10.0	10

Code[5]	Name	Depreciation Schedule (percent)	Orientation Period (years)
	Class 3. Energy-related and Driving Machinery and Apparatus		
346	Sources of Electrochemical current	20.0	5
354	Power condensers, parts of assembly distributors and lightening rods	5.0	20
356	Converters (rectifiers) with over 0.1 kilowatt capacity	5.0	20
357	Control panels	5.0	20
359	Electric motors	8.0	12
361	Rotating current sources	4.0	25
362	Transformers and high capacity choke coils	5.0	20
364	Converter station units	5.0	20
365	Building and tower transformer stations and building switching stations	5.0	20
366	Source generating sets and electrical driving systems	5.0	20
426	Pumps	8.0	12
427	Compressors and volume air pumps	6.0	17

429	Air technology apparatus	7.0	14
432	Cooling and freezing equipment	7.0	14
436	Water treatment equipment	7.0	14
482	Piston motors	6.0	17
483	Industrial and shipboard boilers	5.0	20
484	Central heating equipment	3.3	30
485	Steam turbines	4.0	25
486	Gas turbines and turbine sets	5.0	20
487	Water turbines	4.0	25
488	Atomic reactors and equipment for atomic power plants	5.0	20
	Portable and mobile class 3 machines and equipment	10.0	10

Code [5]	Name	Depreciation Schedule (percent)	Orientation Period (years)
	Class 4. Working machines and equipment		
363	Industrial electrical heating equipment	7.0	14
414	Power hand tools	25.0	4
431	Driers	7.0	14
433	Filling and packaging machines and machines for adjusting packaging	8.0	12
434	Fired industrial ovens (exclusive of those for ceramics)	5.0	20
435	Equipment for pumping and measuring liquid fuels	7.0	14
463	Domestic ships and floating equipment	8.0	12
492	Machinery and equipment for underground mining	17.0	6
	Infield 492, conveyor belts	25.0	4
493	Extraction equipment for underground mines	4.0	25
494	Machinery and equipment for coal and ore treatment	7.0	14
495	Digging wheel excavators and overburden dumping machines	5.0	20
496	Machinery and equipment for geological exploration	12.0	8
497	Equipment for extraction and treatment of peat	6.0	17
498	Machinery and equipment for preparation of blast furnace charges and production of raw iron	5.0	20
499	Coking plant machinery and equipment	5.0	20
501	Steel factory machinery and equipment	5.0	20
502	Rolling equipment	5.0	20
503	Foundry machinery and equipment	6.0	17

Code[5]	Name	Depreciation Schedule (percent)	Orientation Period (years)
506	Social equipment mainly for chemical and food industry	6.0	17
	In field 506, gasometers	3.3	30
507	Machinery and equipment for chemical industry	7.0	14
	In field 507, gas plants	5.0	20
508	Machinery and equipment for production and processing of cellulose, paper, and glues	6.0	17
509	Machinery and equipment for processing rubbers and plastic materials	7.0	14
512	Machine tools (exclusive of machine tools for wood)	7.0	14
513	Forming machines for metals and plastics	7.0	14
	In fields 512 and 513, numerically controlled machines	10.0	10
514	Machines and equipment for welding, soldering and cutting metals	8.0	12
515	Surface finishing equipment	8.0	12
516	Machinery and equipment especially for machinery production and metallurgical accessories	10.0	10
519	Machinery and equipment for the woodworking industry	10.0	10
521	Machinery and equipment for the glass industry	7.0	10
522	Machinery and equipment for textile and clothing industry	6.0	17
	In field 522, industrial sewing machines	14.0	7
524	Machinery and equipment for leather goods industry	6.0	17
525	Machinery and equipment for printing and book industry	7.0	14

Code[5]	Name	Depreciation Schedule (percent)	Orientation Period (years)
526	Machinery and equipment for sugar factories, breweries, malt plants, distilleries, brandy plants, liqueur works, wine processing, yeast, mold, vinegar, acids, enzymes, and fat production, starch factories and potato drying facilities	7.0	14
527	Machinery for processing of milk, eggs, grain and fodder, flour, meat, fish, tobacco, for production of chocolate, candies, and canned foods	6.0	17
533	Machinery and equipment for earth moving, construction, and road work	14.0	7
534	Power shovels and bucket ladder excavators	10.0	10
535	Machinery and equipment for processing nonvegetable materials	7.0	14
536	Agricultural machinery and equipment	10.0	10
	In field 536, machinery and equipment for fertilization and plant protection	20.0	5
538	Machinery and equipment for public eating and sales	7.0	14
539	Equipment and implements for dry cleaning, washing, ironing, cleaning, barbering, and hair dressing	10.0	10
541	Heating and boiling equipment	10.0	10
544	Household sewing and weaving machines	7.0	14
	Class 5. Instruments and Specialized Technical Equipment		
348	Lighting equipment	20.0	5
382	Equipment for cable telecommunication	5.0	20

Code[5]	Name	Depreciation Schedule (percent)	Orientation Period (years)
383	Equipment for radio and television communications	12.0	8
388	Mechanical measuring instruments (excluding weights and timers)	7.0	14
389	Electrical measuring instruments (excluding timers)	8.0	12
391	Electronic and electron microscopic measuring instruments	17.0	6
392	Optical-mechanical instruments (including equipment for the processing of film and photographic materials)	10.0	10
393	Scales (excluding laboratory and home scales)	7.0	14
394	Timing instruments	7.0	14
395	Machines and instruments for determining properties and defects of materials	7.0	14
396	Scientific and laboratory instruments and vacuum equipment	10.0	10
397	Health technology including instrumentation	8.0	12

404	Signalling and security equipment	5.0	20
405	Instrumentation for automatic regulation and control	8.0	12
409	Gauges and equipment for measuring geometric sizes	8.0	12
425	Industrial lubricating equipment	12.0	8
	Class 6. Transportation Assets		
429	Air-technical equipment	7.0	14
444	Delivery trucks and personal cars	12.0	8
445	Trucks and their specific modifications	12.0	8

Code[5]	Name	Depreciation Schedule (percent)	Orientation Period (years)
446	Trailers and semi-trailers	12.0	8
447	Buses	17.0	6
448	Trolleybuses and electric buses	9.0	11
449	Fire trucks and fire apparatus (fire prevention assets)	6.0	17
451	Single track motor vehicles and their specific modifications and trailers	17.0	6
454	Equipment for technical service for transportation assets	7.0	14
456	Electric locomotives	4.0	25
457	Motorized and steam locomotives (excluding steam)	4.0	25
	In fields 456 and 457, mine locomotives	10.0	10
458	Rail cars for passenger transportation	5.0	20
459	Rail cars for freight transportation	3.0	35
	In field 459		
	--mining carts	17.0	6
	--large capacity mining carts	5.0	20
463	Domestic ships and floating equipment	3.3	30
464	Sea-going ships and ships for mixed service	5.0	20
465	Airplanes	14.0	7
	In field 465, aircraft propulsion units	25.0	4
468	Cranes	6.0	17
469	Hoisting mechanisms	6.0	17
471	Elevators	6.0	17
472	Transportation equipment for movement of loose materials	6.0	17
473	Equipment for transportation by cable	6.0	17

Code[5]	Name	Depreciation Schedule (percent)	Orientation Period (years)
474	Equipment for loading operations	6.0	17
	In fields 468 to 474, equipment for construction assembly work	14.0	7
475	Carts	17.0	6
476	Transport equipment for piece materials	7.0	14
477	Metal transport assets for palletization and containerization	17.0	6
531	Wheeled and caterpiller tractors	8.0	12
	In field 531, special forest tractors	17.0	6
	Class 7. Inventory		
384	Radio and television receivers and reproductive apparatus	12.0	8
478	Equipment for the storage of piece merchandise	6.0	17
537	Technical assets for mass entertainment	12.0	8
542	Electrical appliances and household refrigerators (excluding heating equipment, light sources and lighting elements)	10.0	10
557	Metal furniture	4.0	25
615	Furniture of wood and other materials (excluding metal)	6.0	17
739	Stage equipment and theatrical needs	6.0	17
742	Musical instruments	10.0	10
744	Sporting goods	10.0	10
	Class 9. Land and Permanent Growths		
094	Permanent stands (excluding forest)	7.0	14

FOOTNOTES

1. Decree number 152/1975 of Laws of the CSSR, concerning the financing of the replacement of capital assets.

2. Section 70 of the commercial code.

3. Section 350 of the commercial code.

4. Section 34 of CSSR government ordinance number 153/1971, Laws of the CSSR, regarding the information system of organizations.

5. Decree number 95/1976 of the Laws of the CSSR concerning the individual classification of capital assets, as stated in the latest regulations.

6. Directive of the Federal Finance Ministry on the billing basis.

7. Decree number 155/1971 of the Laws of the CSSR concerning the inventorying of economic assets.

8. Decree number 156/1971 of the Laws fo the CSSR, concerning the disposition of national property.

9. Decree 23/1964 of the Laws of the CSSR, which accompanies law number 22/1964 concerning the documentation of real property, as stated in decree number 133/1965 of the Laws of the CSSR.

10. Decree number 90/1972 of the Laws of the CSSR concerning the financing of certain apparatus for the social needs of enterprises, and for certain activities of state economic organizations and foreign trade organizations.

11. Section 18 of law number 134/1970 of the Laws of the CSSR concerning the rules of the federal budget of the Czechoslovak federation and the principles of frugality with the budgeted assets of the budget of the federation and the republics (budget regulations).

12. Decree number 85/1976 of the Laws of the CSSR concerning a more detailed modification of territorial administration and construction practice.

DEADLINES SAID CLOSING IN ON 'KONZORCIUM' GAS PIPELINE

Bratislava PRAVDA in Slovak 6 Aug 80 p 2

[Article by Jan Dulin, editor of PRAVDA: "Time Is Running Out and Deadlines Call for Action--The Construction of the Konzorcium Gas Pipeline Demands Stepped-Up Activity"]

[Text] Kosice (By our editor, Jan Dulin)--Although the history of the transit gas pipeline system in our country began less than 10 years ago, last year we noted that 100 billion cubic meters of gas had already been transported. The capacity of the system continues to grow and will be considerably expanded by a third line--the Konzorcium gas pipeline now under construction.

Last year a 336-km section of the total length of 909 km had been completed and put into operation, and additional sections now being prepared for operation include new turbosets in compressor plants. At present, however, it is evident that the unfavorable weather conditions particularly in East Slovakia, has retarded the pace of the construction work so much that the October deadline for the completion of the entire construction project is in jeopardy.

Challenge of the Assembly Workers from the Ceskomoravsja-Kolben-Danek

Comrade Vojtech Littera, the chief of No 1 construction area in the Transit Gas Pipeline syndicate in Prague, says: "The task of delivering the line sector of the gas pipeline in October of this year is based on concluded agreements concerning Soviet gas deliveries. For that reason we are striving to meet it. The hub of operations in East Slovakia is the compressor plant in Jablonov, where we are scheduled to deliver four turbosets. We have organized a special administrative staff which is in charge of the schedule of operations and deals with urgent problems."

The work of the managing staff led by Comrade Littera has been successful. Turbosets Nos 11 and 12 were delivered by the CKD [Ceskomoravska-Kolben-Danek] in Prague--the general supplier of technology--in July, ahead of schedule. The recent aktiv called by the construction-wide committee of the Communist Party of Slovakia with the deputy director of the Transit

Gas Pipeline communal enterprise, Engineer Tibor Kubini, participating, also expressed appreciation for their innovative approach to all suppliers and workers in the group of investors, but the expression of gratitude was not all. The assembly workers again demonstrated their determination to deliver two additional turbosets ahead of schedule, as soon as October.

Their initiative is of particular importance because it guarantees the transport of the required amount of gas even before the delivery of the entire line is completed.

Construction work on the fourth building of the compressor plant in Velke Kapusany is proceeding concurrently with this task. There the Chemkostav of Humenne must definitely speed up the fulfillment of its objective tasks. Furthermore, it must improve its performance in the construction of the third building in Jablonov; it does not have to go far to look for an example to emulate, because the Hydrostav of Kosice has done excellent work on the same construction project.

Water and Rock

While work on the projects to construct compressor plants has been progressing on the whole successfully, a rather serious situation has developed on the tract of the gas pipeline. Last year's success and this year's fulfillment of the resolutions made by the welders of the Engineering Construction Works in Kosice in general gave rise to optimism; after all, the successive deadlines for the projects from the eastern border up to Jablonov had been met ahead of schedule, and all that was left for completion was a 16-km section. The plans and socialist pledges made by construction workers, however, were jeopardized by the rains. The soggy ground in the East Slovakia lowlands and high water conditions hampered operations connected with the spanning of rivers because the gas pipeline will cross the Ondava and Laborec rivers with an inverted siphon in their riverbeds. Thus far, the delay in the stipulated schedule of construction may not seem excessive. Nevertheless, the completion of the work in this part of the construction project has been postponed until the end of this year.

The most alarming situation, however, has developed in construction project 303, whose 27-km-long second section will cross the Silica Plateau. The Metallurgical Works in Kosice, as a subcontractor of Sigma in Prague, still has more than 10 km of trenches to dig. Drilling and blasting operations are proceeding very slowly, the applied capacities are insufficient, and the deadline set for pumping the gas into the pipeline is now no longer realistic. It appears that this very section will be crucial for the completion of the entire construction project because tasks are being successfully fulfilled in the okreses of Rimavska Sobota and Lucenec with regard to concrete results, the timetable and the stipulated volume. It is therefore quite correct to demand that the Metallurgical Works Corporation reinforce the capacities of its drilling technology and accelerate its operations. It makes no difference that the construction workers were late starting the work there. The complexity and difficulty of the

construction work on the highland plateau had become fully evident even during the construction of the first two lines of the gas pipeline, and thus they could not come as a surprise. The workers of the general supplier, Sigma of Prague, must consider the consequences of their failure to meet partial deadlines. Under the current unfavorable conditions it is of no avail to search for apologies; it is necessary to find a common language and an expedient solution. Every delay in the construction in one section negatively affects the completion of the work in other parts of the gas pipeline, and influences the subsequent technical and biological reclamation of the land as well.

ENERGY MINISTER OUTLINES FUTURE ENERGY PROBLEMS

Leipzig ENERGIETECHNIK in German Vol 30 No 7, Jul 80 signed to press 20 Mar 80 pp 241-245 manuscript received 20 Mar 80

[Edited version of plenary presentation by Wolfgang Mitzinger, GDR minister for coal and energy, at Fifth Scientific Conference for Energy Management, Zittau Engineering College, 14-16 November 1979 in Zittau: "The Importance of the Planned Development of Coal and Energy Management Capacities and the Efficient Use of Energy Sources in All Social Areas To Meet the Growing Energy Requirement of the Socialist Society in the GDR"]

[Text] In the 30 years of the existence of the first worker and peasant state on German soil, as well as with the successful development of our country as a stable factor for peace in the heart of Europe, as the home of the revolutionary traditions of the German working class and as one of the 10 developed industrial nations of the world, demands on energy management have grown constantly.

The problems of providing a stable supply of fuels, electrical energy, gas and thermal energy to the inhabitants and the economy, however, have at no prior time been so much the focal point of social interest as is the case today. More than ever before, the effective production and use of energy--and thus the responsible activity of miners and workers in the energy field, of scientists, engineers and economists in the coal and energy sectors, as well as of all workers in the GDR who in one way or another determine the degree of efficiency of energy conversion and use as a result of their work--has obtained a high degree of political priority. It is of decisive economic relevance for the successful realization of our goals of full employment, public welfare, growth and stability.

As was established scientifically at the Ninth SED Party Congress, assuring the raw-materials and energy base for our country is of fundamental importance for the development of productive forces and for construction of the material and technical base of socialism and communism.

Primary tasks are to increase labor productivity and effectiveness of work in our society, to develop the economy proportionally and to strengthen the material and technical base of the economy of our country. Resulting from this are the constantly growing requirements placed on managing coal and energy in the GDR.

Today, the requirements for meeting energy demand have taken on completely new dimensions. They are the result of current conditions on the international market which are characterized by enduring and continuing processes of price increases for raw materials and energy sources. But they are also the consequence of the problems and rising costs for exploring, mining, converting and transporting domestic energy sources.

Our consistent course of fulfilling the main task, namely the unity of economic and social policy, directly includes the daily, interference-free supply of fuel and energy. Because the material and cultural needs of the citizens can only be satisfied with the aid of certain energy sources, thepeople evaluate the successful implementation of the energy policy of our party and of our socialist state--a policy developed by the Eighth Party Congress and reaffirmed by the Ninth Party Congress--primarily by how the growing needs in fuel and energy are net on a secure and stable basis at all times and under all conditions.

Fuel and energy supply has a high political priority because energy management problems go well beyond the national framework and today already play a decisive role in determining the foreign policy of states. In no region on earth can the problems of raw materials, fuels and energy be solved by one country alone. The capitalist world has been shaken by a profound energy crisis as part of the general crisis of capitalism.

Up to now only the socialist nations, unified in the Council for Economic Mutual Assistance, have been capable of solving their energy problems without the turmoil of such crises. This does not mean that our development is proceeding without problems. But all socialist countries are making great efforts to expand their own raw-materials, fuels and energy base and have experienced the realization of important joint projects in this area. In recent times alone, proof of these efforts can be found in such important projects as the completion of the 750-kV [kilovolt] line between the Soviet Union and the Hungarian People's Republic or the "Soyuz" natural gas pipeline, for which our contribution was the "Druzhba" line. Since 1979, electricity and Soviet natural gas have flowed into our republic through both lines.

The Agreement on Specialization and Cooperation Between the GDR and the USSR until 1990, which was signed on the occasion of the state visit of the general secretary of the CPSU Central Committee, Comrade L. I. Brezhnev, honoring the 30th anniversary of the founding of the GDR, establishes that we will continue on this path in the future and will continue to expand it.

More clearly today than at any time previously do we realize the great economic importance of the fact that our party and state leaders have constantly devoted a great deal of attention in their economic policies to the development and expansion of the domestic energy and raw-materials base as well as to the assurance of a stable supply of energy in the 30 years of development within the GDR.

After 1945, over 30 surface-mining sites as well as 6 new briquette factories, with an annual capacity of around 15 million tons of brown coal briquettes, were established in our socialist worker and peasant state. Today we are producing around 2.4 million tons of coke annually from our domestic brown coal in two brown coal high-temperature coking facilities which are the result of the creative work of scientists, technologists and engineers as well as of our state's construction and assembly workers. Today, for example, it takes us barely 6 months to mine the same quantity of crude brown coal as it did in the founding year of our republic.

In the 30 years of the GDR's existence, production of electricity has been increased to over 500 percent. The largest turbine in 1949 had a standard capacity of 35 MW [megawatts], whereas today we are producing electricity with power plant blocks having a capacity of 525 MW as the result of creative performances by our and Soviet scientists, engineers and machine builders.

Today we are producing in 3 months' time the same amount of city gas as we did in the entire year of the founding of our republic. This results primarily from the development of highly productive procedures for gasification and degasification of domestic crude brown coal as well as the use of our own and imported natural gas for city gas production.

Together with our Soviet friends and comrades, we established a completely new industrial branch, namely the natural gas industry of the GDR, with a current production level of around 9 billion m^3 per year.

In the 30 years of the power of the workers and peasants, a high-performance electricity network has been created for our republic with transmission voltages of up to 380 kV and, as part of the "Frieden" Unified Energy System, up to 750 kV with transmission capacities of over 2,000 MW. Our energy system is thus solidly integrated with those of CEMA member states by means of numerous intermediate system linkages.

The energy policy of the GDR is clearly determined by the resolutions of the Ninth SED Party Congress for the coming years and rests on three important pillars.

First, the needs of the people are to be met by maximum use of our own raw-material and fuel resources in line with the growing of fuels and energy, and planned growth as well as intensification in all branches of the economy of the GDR are to be assured.

Second, specific fuel and energy consumption is to be reduced even further by the continued rationalization of the processes of energy conversion, transmission and use.

Third, on the basis of a consistent realization of the comprehensive program of socialist economic integration, we shall continue to deepen the interrelationships between our economy and the economies of the USSR and the other CEMA member nations.

The implementation of these three premises of our energy policy has also affected the continuous expansion of the fuel and energy base of the German Democratic Republic in the past few years.

The brown coal industry occupies the key position in our country for meeting the growing energy needs of our society.

For meeting the growing energy requirements in the period 1976 to 1980 alone, 13.6 million tons of crude brown coal, 2.8 million tons of brown coal briquettes, 350 kilotons of brown coal high-temperature coke as well as over 1 billion m^3 of city gas were made available for the people and the economy. These amounts exceeded the targets of the 1976 - 1980 Five-Year Plan. Playing a major role here were applied scientific techniques in surface mining, such as capacity-increasing remodeling of overfurden removal bridges and excavators, the development and application of highly productive maintenance procedures, the improvement of drainage technologies or the continued mechanization of auxilliary and secondary processes, with a simultaneous reduction in heavy physical labor.

In the briquette factories as well, the conversion of research findings into practice contributed to a continued increase in the capacities of drying facilities by using an optimum methodology, to the complex mechanization and partial automation of production processes or to the increase in the life spans of high-wear parts for the purpose of rationalizing the production process.

It led to an increase in labor productivity in briquette production by about 9 percent in the last 3 years in comparison with 1975.

Our socialist society made large amounts of funds available in the past few years for the increased use of domestic crude brown coal, including follow-up investments in the territory in connection with the development of surface mining. In the last 3 years alone, more than M 5.8 billion marks were made available for the establishment of new surface mining capacities, in part as a substitute for exhausted coal deposits, for the reconstruction of refinement facilities as well as for the expansion of workshop capacities. It was and is a main objective of scientific-technical work, in the project-planning process as well as in the realization of investments, to use these funds as effectively as possible.

The experiences of the winter of 1978 and 1979 show that massive scientific-technical as well as organizational tasks still have to be solved in order to assure a high degree of stability and efficiency in all surface mining operations at all times and under all weather conditions. The flow of coal to the power plants, briquette factories and gas production plants, especially under severe weather conditions, may not be interrupted at any time.

Therefore, our work in the recent past has been directed toward the improvement of surface mining technologies and the operating regimen in the in the surface mines, especially with respect to the following conditions:

Implementation of scientifically based technologies between increasing the pace of overburden removal and increasing raw coal mining;

Adaptation of management and equipment technology in the surface mines to possible extreme weather conditions;

Development of scientific-technical technologies for assuring a hort-term, priority mining of coal under adverse weather conditions.

Other tasks for increasing the certainty of raw coal supply for large power plants have been accomplished--for example, expansion of coal storage areas in a few power plants, the additional use of railcar discharge equipment, the construction of extraction platforms of the establishment of defrosting walls and halls.

In this connection we believe that research and theories in the management of power plants will have to concern themselves much more in the future with the optimal mastery of large mass flows and with the requirements placed on the organization of work, even under extreme weather conditions. We need more scientific-technical solutions for assuring a high degree of stability for power plants at all times and solidly trained cadres that are capable of managing the power plants safely and stably, even under extraordinary conditions, with as great a degree of availability as possible.

About 50 percent of the still available coal deposits that can be mined in the GDR are in the surface mines that are already in operation or are to be opened by 1990. Of the remaining deposits, which either have not yet been opened up or included in the mining plans up to 1990, about 10 percent are salt coal deposits, any processing of which causes considerable technological difficulties because of the relatively high alkali content. We are also expecting an important contribution by scientists and engineers for solving this problem.

The further development of our brown coal mining efforts in the period around 1990 and thereafter will be determined not only by the useable duration of the deposits and the necessity for ensuring an adequate life span of the large consumers that have been created, such as power plants

and refinement facilities. It will also be determined by the then available approaches and the prerequisites created by deposits for establishing mining capacities. Therefore, our long-term concepts assume that up to 1980, raw coal mining will continue to increase. The period from 1980 to 1985 has a special strategic importance for the furhter impact of the energy management structure in our republic, aimed at the following considerations:

achievement of a considerable reduction in the use of heating oil through the increased use of domestic raw brown coal; and

Assurance of the prerequisites for an increase in the mining of brown coal in the next decade to 300 million tons per annum.

The great importance of the rapid development of brown coal mining for effectively meeting the growing energy needs of our socialist society can also be seen in the fact that in comparison with 1971, the prices on the capitalist world market for crude oil increased to 1,029 percent and to 179 percent for hard coal in 1979. For example, if one calculates the prices for these energy sources in terms of calories, then crude oil costs 4.5 times more than raw brown coal and 2.7 times more than brown coal briquettes. In the case of hard coal the price is more than double that of briquettes. It can clearly be seen from this comparison that it is very important for our republic to increase our own uields of energy sources on the basis of our domestic raw brown coal and to conserve all energy sources as much as possible.

The importance of brown coal for the production of electricity is illustrated by the power plant structure. Despite the growing proportion of nuclear energy in total electricity production figures, present calculations show that in 1990 over 70 percent of the total production of electricity will have to be supplied by brown coal-fired power plants.

The use of raw brown coal for producing heat is occurring to an increasing extent through the expansion of the district heating supply system.

In concurrence with the housing construction program, a series of new heat facilities, thermal power plants and industrial power plants using brown coal will appear in the coming years.

This fact emphasizes the special importance of raw brown coal for meeting energy needs, for the stable availability of electrical energy helps determine to a decisive degree the dynamic development of the economy as well as the rise in the people's standard of living.

In the past few years we have also ambitiously expanded the power plant base in our country, and alone in the period from 1976 to 1978, capacities were increased by 11.5 percent.

In close socialist cooperation with machine builders, workers in the electrical engineering field as well as construction workers, and as part of the socialist economic intergration with the Soviet Union and the other socialist countries, we were able to assure the scheduled start-up of new capacities with a high degree of supply efficiency. Some of these new capacities are the power plants at Hagenwerder III and Boxberg as well as the "Bruno Leuschner" nuclear power plant.

But also decisive for meeting the electricity needs of the GDR was the fact that the average availability of power plant capacities was increased by 2.4 percent in the past 3 years. In this effort it was primarily the scientific work and the worker initiatives that contributed decisively to peak load methodologies, to the application of productive maintenance technologies and to extension of the life spans of the plants.

On the basis of the resolutions on the "Theories Related to Overcoming the Consequences of Extreme Weather Conditions in the Winter of 1978/1979," our work in the past few months has been directed toward creating greater assurances for supplying electricity to the people and to the economy.

The solution of two decisive tasks was emphasized in our work:

First, there were efforts to create the necessary prerequisites so that the availability of power plant capacities, which are the basis of supply balances and plans, is achieved at all times and under all conditions.

Second, we concentrated on achieving a higher degree of supply assurance by projecting demanding objectives for the most economical use of electricity in industry as well as in all other areas of our life. These objectives assume the reduction of the previously planned consumption of electricity by an average of 5 percent by means of conservation without having any effect on production and the standard of living.

To assure a high degree of stability of capacities in power plants, the work has to emphasize the following conditions:

Precise adherence to the operational regimen, especially the operating and control regulations;

Consistent implementation of the repair and remodeling programs for power plant outfittings.

What we need is a greater contribution by science and technology for a high level of management in the power plants to preclude disruptions and accidents.

For example, this involves the development and use of safety equipment which precludes improper procedure and incorrect actions right from the beginning.

But in the determination of necessary maintenance schedules and applications in energy installations as well, there presently are still too few scientifically based and tested instruments and methods which can be used to determine reliably the state of wear and the life span reserve of power plant facilities and electricity transmission systems. For this reason, the methods and procedures of technical diagnostics are to be advanced at a considerably faster pace and applied practically in larger areas of application in order to preclude discontinuities in the electricity supply process as much as possible.

But we also need scientific-technical solutions for a higher level of productivity and effectiveness of the maintenance processes in power plants which will lead to a further reduction in repair times, with a simultaneous reduction in the amount of work necessary and the maintenance of high quality standards.

The main way to achieve the objectives we have posed for securely meeting the growing demand for electricity in our socialist society is and remains the continued expansion of socialist intensification, with a simultaneous acceleration of scientific-technical progress as well as the systematic construction of new capacities.

Continuing to design the developed socialist society in the GDR simultaneously includes new and greater tasks for science and technology. We especially need results in research and development from our institutes and universities, results which set world standards and which can be transferred into practice within the shortest possible period of time.

Science and technology are integrated components of management and planning in the development of the fuel and energy base. We derive our development objectives from the information gained thereby for the planned design of the energy base of our socialist society.

But simultaneously we also determine the requirements to be placed on science and technology for assuring the growth of performance, productivity and effectiveness from the requirements resulting from the continued designing of the developed socialist society in the GDR.

With respect to the continued expansion of the power plant base in our republic, access to capacity will be determined primarily by the new brown coal power plants with 500-megawatt block units and by nuclear power plants with large block units. The close cooperation with the USSR in constructing these power plants assures the comprehensive realization of scientific-technical progress as well as the smooth adoption of the most advanced experiences in power plant construction in the USSR, a country which occupies a leading position in the world.

The output structure is being improved gradually with the continued expansion of our power plant base. Completion of the pump storage plant in Markersbach, with 1,060 MW in 1981, will be a decisive component. Together with the existing pump storage plants and gas turbine plants, the percentage of pure peak power in total power will increase from 6.1 percent in 1975 to about 10 percent in 1985. With the construction of industrial and thermal power plants, we will be making even greater use of the energetically and economically advantageous heat-to-power coupling method using the building-block solution for thermal power plants and industrial power plants, now being developed and constructed, with 320-tons per hour steam generators using raw brown coal and 60-MW bleeder back-pressure turbines. This type of thermal power plant will determine the profile of heat supply in the coming decades. This is of decisive importance for the ambitious realization of the housing construction program as the core of the SED's social policy program.

Alone in the period from 1976 through 1980, over 93 percent of all newly constructed housing is being outfitted with modern heating systems; of these, around 78 percent use district heating.

The continued development of the electricity system, however, also requires the continued systematic expansion of the main transmission lines with 220/380 kV in connection with the power feed from the new power plant locations. The 380-kV system will be designed as a beam network until about 1980 and then be increasingly interlaced with cyclical circuits. The 380-kV system is related to the gradual construction of a 750-kV system-forming network of the Unified Energy System of the CEMA member states. The first step in this direction was the establishment of the 750-kV intermediate system connections between Vinnitsa (USSR) and Albertirsa (Hungarian PR).

We have achieved a marked scientific level in calculating and optimizing the expansion plans of electrical mains. This level must also be achieved in the management of electrical transmission systems.

Microelectronics and computer technologies are providing us with important assistance on this point, as has been confirmed by the first cases of application.

But in this area as well, the pace has to be accelerated and a closed concept for automating the associated electricity system has to be developed.

Along with the increase in the performance of coal and energy management by intensifying existing facilities and building new capacities, growing importance is being accorded to the rational and economical use of energy as a fixed component of our socialist energy policy.

The rational use of energy and the consistent reduction in avoidable energy-conversion, transmission and application losses are increasing the leeway in economic growth considerably and are thus having a direct affect on the successful continuation of our economic and social policies which are directed toward fulfilling the main task.

The consistent adaptation of energy needs for production to technically and economically based consumption values that are oriented toward the peak scientific-technical level, and assurance of the economical and rational consumption of energy in all other areas of social life, especially for room heating, lighting and transportation, are the tasks which will continue to require intensive penetration by science and technology. Initial results have already been achieved.

The growth rate in the national income of more than 5 percent per annum was achieved in the past few years with a utility energy growth rate averaging only 2.0 percent. The specific expenditure of primary energy per mark of gross production was reduced by aroudn 25 percent. By means of economic rationalization in energy and an improved energy sources structure, from 1971 to 1978 energy conservation was achieved which corresponds to about 58 million tons of raw brown coal.

The high degree of effectiveness of economic rationalization measures for energy is expressed in the return flow time span for investments averaging 1.5 years.

These few figures do show clearly that the rational use of energy is not a matter that was born out of necessity but rather is a rule of socialist management derived from the law of the economy of time.

It is objectively necessary here to place the question about reduction of energy losses in the management of coal and energy at the top of the list of all considerations.

Up to now, the specific index figures for energy consumption have been undercut for a whole series of energy-intensive processes, including gas and coke production as well as the production of briquettes. The core problem, however, consists in achieving a considerably faster pace for reducing the specific fuel-to-heat consumption for electrical energy production, especially in our large power plants.

Along with conserving fuels and increasing degrees of energy conversion efficiency, the use of incidental and environmental energy also plays an important role.

Undoubtedly, in the GDR good results have already been achieved in the use of secondary energy sources. Waste xylite-bearing wet ash, coal-mix products and sump products as well as brown coal briquette dust have been used almost completely. This also applies to liquid and gaseous waste fuels. The waste energy sources used at present are equivalent to about 20 million tons of raw brown coal. If we consider that almost half of the waste energy sources are being used, then the comparison of both values indicates the importance of the greater use of waste energy sources for our republic's primary energy balance.

The higher requirements placed on a rational and economical use of energy, as was dictated to us with the resolution of the GDR Council of Ministers, dated 13 September 1979, are the bases for the 1980 plan and for conducting the socialist competition. This can be perceived mainly by using the following comparison of figures: the annual growth rate in primary energy source supply from 1971 to 1976 was 2.0 percent and from 1976 to 1979 an average of 2.7 percent per year, but the 1980 plan estimate projects economic growth with a growth rate for primary energy of 1.7 percent.

The tasks to be solved in the coming period are clearly defined in the resolutions of the party and government for the continued development of the fuels and energy base in our republic.

MANPOWER REGROUPING, RETRAINING MEASURES DISCUSSED

Budapest FIGYELO in Hungarian No 33, 13 Aug 80 p 1,6

[Article by Dr Iren Szabo: "Labor Management. Regrouping, Retraining and Skills"]

[Text] Technological and economic development, combined with a changing product structure, affects workers' skills in a number of ways. On the one hand, it requires skills that are convertible (i.e., include a number of trades and job assignments) and are based on a higher educational level. On the other hand, it requires regrouping and retraining of a substantial portion of employed skilled workers.

At the present time, the skilled labor force of enterprises can be classified according to the workers' credentials as follows: the so-called "in-house skilled workers" (those who have completed 8 grades or less); those who have obtained their credentials by completing courses after work (also with a 8th grade education or less); skilled workers who have graduated from training institutes (8 grades plus 2 or 3 years of training); and, finally, skilled workers with a high school diploma.

Worker's Certificates From Many Sources

Most of the so-called "in-house skilled workers" have spent a long time in the same job at the same enterprise. They have accumulated a great deal of experience. In general, their theoretical knowledge is on a low level, their skills are narrow, but they are competent and know a great deal about local conditions. Convertibility of their skills is narrow: it is restricted to jobs not much different from the one they have learned.

Skilled workers who have completed courses along with their work differ from the preceding category in that their worker's certificates must be accepted by all enterprises. As a result, this group has more mobility. Their convertibility within the enterprise is in most cases restricted to jobs that were part of their trade at the time when they took their courses.

It must be noted that participation in vocational training by those already in the work force declined between 1960 and 1974.

Graduates of vocational training institutes are somewhat better acquainted with theory. This provided a better basis for further technical training. This is especially true for those who have received 3 years of vocational training after finishing eighth grade. The number and percentage of vocational institute students enrolled in advanced programs increased greatly between 1960 and 1974. Their percentage rose from 0.2 percent during the 1964-65 academic year to 47.2 percent in 1973-74. Expansion of this system creates better conditions for further training, raising the general and special skills of workers and converting skills.

Skilled workers who have obtained their certificates after finishing high school have received technical training over a much shorter period (the difference is 1 or 1.5 years). This is because they have learned about theory in the high school. As a rule, they are easier to "convert" than those without a high school diploma, precisely because of their theoretical knowledge.

The training of graduates of technical high schools differs from that of other high school graduates mainly in that their basic knowledge of humanities and natural sciences is on a somewhat more modest scale, while their basic knowledge of technical matters is more extensive. On the other hand, their work experience is less than that of vocational school graduates. Their absorption into the workplace involves more problems, but they are highly "convertible," especially in jobs requiring a lot of theory.

One can assume that with the increasing integration of technological processes in the future there will be an increasing need for workers who have received training in a number of interrelated skills in a technical high school where they have acquired knowledge of a large segment of the production process.

Technical development and changes in the product structure over the next 10 to 15 years will both require a great deal of realignment and regrouping. The quality, composition and adaptability of the work force will have a major effect on the rapid and smooth fulfillment of these tasks.

Without an Eighth Grade Education?

The fact is that the education and training of manual workers has undergone major changes in the last 30 years. There is an intimate relationship between age composition and educational level because young people have had much better opportunities to study and, of course, because the age groups with a lower educational level are gradually leaving the productive work force. Development of the workers has a similar effect: more and more are finishing elementary school; the number of skilled workers with high school diploma is increasing and teaching in technical high schools is increasingly being coordinated with vocational training.

Nevertheless, we must know that, alongside the laudable accomplishments, about one half of active wage-earners doing manual work have not completed elementary school. This situation, unfavorable as it is, is further complicated by the fact that about 30 percent of those who have not finished elementary school (500,000 people) belong to the 15 to 30 age group. This is especially noteworthy because these people will take part in socially organized work for up to 20 to 30 years. The situation is further exacerbated by the constant "regeneration" of the group that has not finished elementary school. Every year, about 12,000 to 15,000 young people exceed the compulsory school age limit without finishing their elementary school studies. This is one reason why, in some trades, it is not possible to insist on elementary school graduation as a prerequisite for adult training. Lack of basic elementary school subjects is a critical point of labor management, retraining and convertibility within enterprises because the theoretical basis of technical training is lacking.

One and one half million people passed the tests to become skilled workers between 1960 and 1973. This represents 80 percent of all skilled workers in 1973. This does not mean, however, that a corresponding percentage of skilled workers finished school after 1960 because some obtained certificates in two or even three trades, others got white-collar jobs after earning their certificates, while a substantial number of young skilled workers took unskilled or other jobs due to financial reasons.

Education and Technology

By analyzing the question from another viewpoint based on the age composition of skilled workers and other data, one can conclude that about one half of skilled workers in 1973 finished training after 1960. This means that about one half of today's skilled workers got their certificates in the 1950's when the number of students increased suddenly, but the financial and personnel conditions of training were, to put it mildly, deficient. (On this topic, more in FIGYELO, No 27, 1980. - Ed.)

At the same time, there were periods when novice workers entered socially organized work in such numbers that the relatively few well-trained professionals were unable to give them any competent direction. As a result, practical experience contributed to problems arising from the low quality of training, rather than remedying them.

From the standpoint of the development of our economic structure one cannot neglect the fact that about 1 million active wage-earners have entered industrial organizations straight from households or agriculture. (55 to 60 percent of today's unskilled or semi-skilled workers are still of peasant origin). In the majority, they have no skills or have only the kind of skills and experience that is largely unnecessary for today's economy. The educational level, skills, technical, organizational and work structure of workers entering industry and construction directly from agriculture and household work as a result of this large-scale realignment was much lower than the general and technical sophistication of the group

they joined. Their adaptability is still slowed by problems accompanying a shift in environment. This has a direct effect on the quality of production, the technology to be employed and the utilization of advanced technology. The technology in use puts certain limitations on the product structure and the quantity and quality of products. In some cases the level of technology in use is beyond the educational level of the work force, which leads to reduced utilization of assets.

Increasing Losses

We must acknowledge rapid development in the area of education and technical training, but we must also pay attention to the facts mentioned. Certain experiences suggest that the workers real knowledge and accumulated experience of manual workers and their resulting productive capacities are lower than one would expect on the basis of data indicating expansion of education and technical training. These experiences provide another proof that young skilled workers with a high school diploma are easily "convertible;" graduates of vocational institutes are relatively more difficult to "convert," while conversion of so-called in-house skilled workers and graduates of courses at the workplace is the hardest.

Thus, there are many who lack the fundamental prerequisites for acquiring more advanced skills. For them, technological shifts and manpower redistribution mean difficult conflicts. Our problems and losses due to structural reorganization are expected to become more acute because, on the one hand, the national economy has too many specially trained workers with a low level of general education who are hardly capable of redirection and retraining. On the other hand, unfortunately only a narrow group of skilled workers has the wherewithal to enable them to satisfy the new requirements.

These facts mean that the leadership and personnel in labor management must face up to new and unusual tasks, one that can be solved only on the basis of thorough analysis and a great deal of technical competence.

PERSONAL INCOMES IN FIRST QUARTER OF 1980

Belgrade PRIVREDNI PREGLED in Serbo-Croatian 15 Aug 80 p 2

[Article by M. Urosevic: "Foundation for Renewed Growth of Real Personal Incomes"]

[Text] In a recent conversation with newsmen of TANJUG Veselin Djuranovic, chairman of the Federal Executive Council, issued the assessment that incomes policy is in conformity with the demands of stabilization policy, but that everything will have to be done to shorten the time of the real drop of personal incomes. This provided an occasion for us to compare figures on the trend of production, hiring, productivity and personal incomes.

In the first 4 months of this year the physical volume of industrial production rose 5.5 percent over the same months of last year, and employment rose 3.1 percent, which means that labor productivity rose 1.6 percent.

Over that same period retail prices, which are used to measure the rate of inflation, rose 26.2 percent and the cost of living 26.5 percent more than in the same months of last year. Nominal personal incomes of employed Yugoslavs increased 17 percent, and the difference between this increase and the rise of the cost of living, which amounts to 9.5 percent, signifies a real drop of personal incomes.

However, it would be wrong to conclude that the burden of the drop of real personal incomes is being equally borne by all employees in all workplaces. It is true that this year the statisticians are late with reports on personal incomes by industries according to the Uniform Classification of Activities and are publishing figures on the principal economic activities--which is considerably more restricted and one-sided--but it is still sufficient to indicate essential characteristics.

Thus, personal incomes in economic activities are lagging 3 percent behind the Yugoslav average, and those of employees in industry and mining, where more than two-fifths of the social product is created, are lagging 5.6 percent behind. The situation in economic activities would have been still less favorable on the average if 2 years ago those employed in the activity

entitled "financial and other services" had not been "shifted" from noneconomic activities to the economy. This transfer consisted of 193,000 employees with personal incomes averaging 30.6 percent above the Yugoslav average.

Employees in noneconomic activities had personal incomes in the first 4 months of this year 15.8 percent higher than the average for the entire country, and those in sociopolitical communities and organizations were 20.8 percent better off.

The level of personal incomes varies from one sociopolitical community to another. The personal incomes of employees in Slovenia were 22.1 percent better than the Yugoslav average, and those of employees in Croatia 7.5 percent higher. In Serbia proper the lag behind the Yugoslav average was 4.8 percent, but we must bear in mind that these figures also include the personal incomes of those employed in federal agencies and sociopolitical institutions and organizations at the level of Yugoslavia, which considerably boosts the average. Personal incomes in Vojvodina lagged 5.7 percent behind the Yugoslav average, those in Bosnia-Hercegovina 9.1 percent, Montenegro 10.1 percent, Macedonia 17.7 percent and Kosovo 20.4 percent.

In addition to these figures, it would be worthwhile if we also had figures on payments per worker from the social service funds of organizations of associated labor.

It is obvious, then, that in the coming period conditions need to be created by raising productivity and output for personal incomes to begin a new real growth.

[Box]

According to the final figures, the average net monthly personal income of employees in the period January-April of this year amounted to 6,636 dinars: 6,436 in economic activities and 7,682 dinars in noneconomic activities.

The ranking of principal activities is as follows:

1.	Financial and other services	8,667
2.	Sociopolitical communities and organizations	8,013
3.	Education and culture	7,798
4.	Health and social welfare	7,288
5.	Transportation and communications	7,102
6.	Crafts and trades	6,998
7.	Housing and municipal services and utilities	6,582
8.	Water management	6,581
9.	Trade	6,518
10.	Industry and mining	6,265
11.	Construction	6,221
12.	Timber and lumber	6,760
13.	Agriculture and fishing	5,760
14.	Hostelry and tourism	5,569

FOREIGN TRADE IN AGROINDUSTRIAL SECTOR, FIRST HALF OF 1980

Belgrade PRIVREDNI PREGLED in Serbo-Croatian 15 Aug 80 p 6

[Article by Milorad Urosevic: "Appreciably Smaller Deficit"]

[Text] The change in the dinar's rate of exchange should objectively stimulate exports and at the same time activate disincentive on imports, while at the same time fulfilling the main condition that sufficient goods be produced primarily to satisfy domestic needs and then also for export at competitive prices. At a time when food is joining petroleum as a commodity in ever greater demand in international trade, this change should also speed up exports of raw and processed foods from Yugoslavia; that is, it should make it possible to continue the favorable trends from the second quarter, when the deficit in the first 3 months was reduced. All of this provided there is enough food to meet domestic needs as well as the higher consumption at the height of the tourist season, which as matters now stand is in doubt.

Actually, imports increased even before devaluation of the dinar: thanks to the sudden jump of sugar prices on the world market, which took away the worries of domestic sugar mills and made it possible for them to sell inventories at very favorable prices, the agroindustrial complex appreciably improved its 6-month trade balance, as can be seen from the figures below.

January-June Period, in millions of dinars

Activity	Exports	Imports	Difference
		1979	
Food processing industry	3,767	3,134	+ 633
Beverages industry	541	61	+ 480
Livestock feed industry	25	83	- 58
Tobacco manufacturing	31	3	+ 28
Field cropping	1,191	5,645	-4,454
Fruitgrowing	56	4,137	-4,081

Table (continued)

Activity	Exports	Imports	Difference
Viticulture	4	14	- 10
Livestock raising	1,147	1,022	+ 125
Fishery	136	224	- 88
Total	6,898	14,323	-7,425
Coverage of imports by exports, %		48.2	
		1980	
Food processing industry	5,678	3,575	+2,103
Beverages industry	685	101	+ 584
Livestock feed industry	28	58	- 30
Tobacco manufacturing	87	2	+ 85
Field cropping	1,997	6,221	-4,224
Fruitgrowing	35	3,814	-3,779
Viticulture	12	22	- 10
Livestock raising	1,227	1,098	+ 129
Fishery	117	222	- 105
Total	9,866	15,113	-5,247
Coverage of imports by exports, %		70.7	

Results of this kind for the first 6 months are very encouraging, providing favorable opportunities are maintained for the agroindustrial complex to continue the tendency of exports to increase more rapidly than imports. We should remember that the coverage of this complex's imports by exports in the first 3 months of this year was only 51.6 percent, as against 50.6 percent in the same months of last year; and also that in the first half of this year the coverage of the entire economy's imports by exports was 55.8 percent and that of the agroindustrial complex (as is evident from the table) 70.7 percent, but it is no sure thing at all that this trend will continue.

There are several reasons for this view of the situation. It is well known, for instance, that this year's harvest of 511,000 cars of wheat (last year only 447,000 cars) is not sufficient to replenish commodity reserves and meet the public's needs this year, so that imports are inevitable once again. Which will drain off considerable foreign exchange. Then there follows the recent decision allowing supplemental import of 10,000 tons of meat, mostly pork, after the import of 35,000 tons of beef had already been allowed, and the decision to halt exports until this September, which will reduce the inflow and increase the outflow of foreign exchange to import food. To this we should also add the shortfall in the planting of corn, sugar beets and sunflowers because of bad weather and also reduce fattening of livestock. On the other hand there are the ever greater needs for food,

so that the amount lacking from domestic sources will have to be obtained through purchases on foreign markets.

When all these circumstances are borne in mind, it is difficult to believe that the agroindustrial complex will continue to have the favorable trends in its commodity trade with foreign countries in the second half of this year. It would be good if this disbelief proved unfounded, but time will tell.

OFFICIAL DISCUSSES ECONOMIC STATUS OF CROATIA

Belgrade KOMUNIST in Serbo-Croatian 5 Sep 80 p 7

[Interview with vice chairman of the Executive Council of the Croatian Assembly Dr Ivan Mecanovic, by Viktor Strkalj: "Still Fiercer Battle and Greater Responsibility"; date and place not given]

[Text] [Question] The balance sheet of the Croatian economy for the first 6 months, in spite of a whole series of difficulties, indicates qualitative changes: exports are growing steadily, the payments deficit is decreasing, and the trend of imports has been halted. The difficulties, of course, have still not been overcome, especially those that come with losses in the economy, and also the decline in the rate of industrial output. There are also the problems on the broad capital investment front, where nearly 6,000 projects are under construction. How do you assess the present moment in the Croatian economy?

[Answer] Developments in the Croatian economy show that the process of stabilization is under way. If we examine what the 6-month account furnishes us, we see, among other things, that behavior has changed in organizations of associated labor, manifested by the most tangible result of a real drop of personal incomes. This is only one of the measures of stabilization, and it seems that it was the easiest to achieve. But now the question is this: Where do we go from here in this area?

Other agreed effects of stabilization have also begun to show up. Regardless of what is happening in production and regardless of how we define these developments, it is our assessment that the social product will show a growth of somewhere above 2 percent. Industrial output is showing a definite tendency to increase, which, however, should not deceive us, especially when we know that the growth rate was quite low in the 7th month of last year. The problems are mainly concentrated in machinebuilding, whose output is about 7 percent smaller than last year, and in shipbuilding, where the drop is 17 percent. We are experiencing something similar in petroleum production and refining, but this is a part of the strategy of consuming less. This means that production in other industries is more or less better than in previous years in spite of the fact that the problem of

substitution of imported raw materials by domestic raw materials is becoming more and more acute.

Losses

In the domain of distribution, as I have already said, there is the significant item of a reduction of personal incomes, which has had the result that funds for expansion of the material base of operation are growing faster than in previous periods by all of about 40 percent. However, an item we must be particularly concerned about is losses in economic activity, which in the amount of 5.8 billion dinars constitute almost one-third of total losses in the Yugoslav economy. It seems to us, nevertheless, that we can correct this, since a sizable portion of the losses are seasonable in nature, as is the case with the loss of about 1.7 billion dinars in hostelry and tourism. However, particular attention and analysis should also be concentrated on the losses arising in petroleum refineries and the production of nonferrous metals. By all appearances the devaluation will result in a "reallocation" of the losses, and we expect that they will remain at the present level up to the end of the year.

It is difficult at this point to provide a precise judgment of what is happening on the investment front, but it is significant that certain of the largest projects such as the Ivanja Reka--Lipovljani highway, the bridges on Krk and at Bogojevo, are already completed.

Incomes

[Question] Can we, then, speak of an optimistic autumn start?

[Answer] What is meant by optimism is a big question. It is a fact that economic difficulties do exist, but at the same time we are today much better organized than we were, say, 3 months ago. In other words, the situation is not such that there is no way out, but at the same time we must take a number of factors into account. Social welfare policy first of all. We feel, for example, that it is a good thing that there has been stabilization in the domain of personal incomes, but we also feel that at the present moment we must see whether this can be taken any further, especially in the case of workers with low income. It is obvious that stabilization is transferring the burden from the economy to a portion of social welfare policy, and this obliges us to very quickly put trends in the domain of personal incomes and the tax system on the agenda. In the conduct of social welfare policy we must, of course, show very great responsiveness. That is, it often happens that an individual with a monthly income of 1 million old dinars is in a much more difficult welfare situation than the man with the lowest income who, however, has 3 hectares of land in the suburbs of Zagreb, Rijeka or Split.

[Question] It is in this context that the datum that wages and salaries constitute only 35 percent of personal income is often referred to in public and even from the benches of the assembly. Is this datum correct?

[Answer] It is not, since, for example, it does not take into it the fact that in Croatia there are about 1.2 million people living on pensions. We might speak about a 50:50 ratio. Though even pensions show the false picture, it is obvious that we must examine very precisely what a "half-and-half" ratio means. I feel, for example, that this jeopardizes labor productivity, which is very unwise. After all, over the last 10 years labor productivity has stayed at the same level, while over that same period we have considerably modernized the capacities of the economy. So, a much improved technology has not resulted in higher labor productivity, it has not led to the introduction of a second, third and some places even fourth shift. On the one hand this is a negative result, but on the other it is the position from which we can make a rapid start; that is, it gives us an opportunity to operate more efficiently. However, we must also be aware of the fact that in certain of our economic steps we are "encouraging" this 50:50 ratio. It is clear that we cannot overcome work "u fusu" unless we strengthen small business even in a situation when it is not possible or society is unwilling to tax it. It must also be clear to us that we have a large number of people working in the public sector who are earning an additional portion of their income as farmers or by rendering tourist services. For certain categories, it is true, this may even be a welfare corrective, but it is beyond all doubt that it puts the "pure" worker in an unequal position, so that often his welfare really is in jeopardy even though he has a relatively high personal income. This means that when we speak about wages and salaries, we dare not equate different things, just as we dare not oppose high personal incomes if they represent work performance. We must, however, conduct a policy which will have the result that employees with high earnings will also make larger social contributions.

Investment Projects

[Question] You mention that there has been a change of behavior in organizations of associated labor. Does this mean instead of crash efforts to overcome the consequences they have begun to correct the causes of present economic difficulties, including "assignment" of responsibility for the losses which have occurred, for bad investments, and so on?

[Answer] Of course the entire effort, especially the most recent measures of the assembly concerning further activities to achieve economic stabilization in Croatia, has been aimed at correcting the causes, which are both complex and manifold. When we speak about investment projects, for example, we must say that the technobureaucratic influence is still strong in this area, but there are also a number of economic reasons for the present breadth of the investment fund in that about 6,000 projects are under construction. For example, anyone who saved money at the very high rate of investments ["inflation" is presumably meant] turns out actually to have been a "poor businessman," while he who spent anticipated earnings has brought it about that even the most foolish investment project has become intelligent after a time, since inflation has in effect made it cheap. However, since miracles cannot be worked in this way, society as a whole is

paying for this appearance of sensible behavior. So, it is a question of a change of behavior throughout the system, and not only in certain of its aspects. Our point of departure should be the fact that we have not altogether managed to achieve the goals we have proclaimed. That is why we cannot escape responsibility by saying, as many do, that "the system is no good," but we must implement it consistently. Consequently, we face a still fiercer battle to put the system in effect and to achieve still greater responsibility in that context.

As for personal responsibility, it would be an illusion to suppose we can solve our problems by naming 10 or 15 individuals, if at the same time we do not correct the causes. This does not, of course, mean that we should not accentuate personal responsibility, especially since we have specific motives for this. For example, in the recent "smothering" of the Ivanja Reka--Lipovljani highway, many republic agencies became involved, but not the Croatian SIZ [self-managed special-interest community] for Highways, which bore the greatest responsibility. Though perhaps this is a trivial example, it is a prototype of what we are experiencing in practice.

Responsibility

[Question] A specific question on the topic of responsibility. How should we interpret the fact that in recent years new plants or plants which have undergone reconstruction are among those with losses? In a recent session of the assembly the figure was presented that 34 organizations of associated labor whose plants have been put into operation in the last 3 years recorded losses amounting to 1.84 billion dinars, which represent 37 percent of total losses.

[Answer] One of the most important factors is certainly that we adopt very short payoff periods for investment projects, so that in the first years there are large repayments of principal and high interest on short-term credit, which in itself is not good. At the same time, we often harbor the illusion that we can build a factory in the middle of nowhere and that it can immediately begin to operate. It is precisely these projects of ours which are "producing" losses, by contrast with those built by work organizations with a certain experience. Of course, it is not merely a question of experience in production proper, but also of experience in marketing, sales, and so on.

Another reason for the losses lies in failure to take into account momentary or long-term developments on the world market. A typical example of this is the Jadral Alumina Plant in Obrovac, which, in my opinion, could be an exceptional producer in 6 or 7 years. At present they are paying for the fact that it was built and put into production at a time when the price of aluminum was low on the world market and even lower on the domestic market.

[Question] If you recall, there was a very stormy debate in the Croatian Assembly about Jadral as a major source of losses, and the possibility of "mothballing" it has been mentioned more than rarely. The situation as you put it is not so "black" as it is frequently portrayed.

[Answer] There is a tendency today that indicates that aluminum will be increasingly expensive. And also, this is perhaps the only product which is cheaper on the domestic market than on the world market. It is obvious, then, that a rise in the price of aluminum would make it profitable to undertake not only surface, but even underground mining. But another problem is that we must undertake the higher phases of manufacturing aluminum, which yield 20 or even 30 percent larger incomes than at present. I do not say that this can be done without upheavals; indeed there will be quite a few more problems in the aluminum complex, but, in my personal opinion, Jadral could become a relatively successful factory in the future.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

ASPECTS OF FOREIGN CURRENCY PAYMENTS AMONG CEMA MEMBERS EXAMINED

Sofia PLANOVO STOPANSTVO in Bulgarian No 6, 1980 pp 46-55

[Article by Pavel Daskalov: "Foreign Exchange Aspects of Bilateral and Multilateral Economic Relations Among CEMA-Member Countries"]

[Text] Determining the nature, place, and role of the specific forms of economic cooperation is of great importance in establishing the nature of integration processes among CEMA-member countries and determining the most effective ways and means for development of economic cooperation among them. Currently, bilateral and multilateral methods are applied simultaneously in intergovernmental economic relations among socialist CEMA-member countries. Since both forms are connected with different national and international institutions, involve different organization of the work, and have different objectives, tasks, and results, legitimately the following questions are asked: How are relations among CEMA-member countries developing, what are the possibilities for combining and interlinking the two forms of economic relations, and what is the optimum relationship for their cooperation.

Long experience in the economic cooperation among CEMA-member countries has confirmed that both organizational forms have their place and basis and that they are closely interconnected and interwoven. A bilateral and a multilateral status are not mutually exclusive. On the contrary, they are interdependent. The use of one of them creates favorable prerequisites and conditions for the utilization of the other organizational form and vice versa. That is why it would be incorrect and one-sided to consider in advance multilateral relations as a superior form of cooperation compared with bilateral relations, or else if priority is given to bilateral methods in the solution of specific economic problems from the practical viewpoint.

The simultaneous use of the bilateral and multilateral methods does not mean, however, that it makes no difference which of the two organizational forms is applied under specific circumstances or in carrying out specific assignments. The specific correlation between the bilateral and multilateral principles in its historical aspect depends on the nature of the problems they are resolving through economic cooperation. The correlation between them is not final or

determined once and for all, but changes depending on the stages of development of socialist economic integration and the objective of the measures to be implemented.

Bilateral relations predominated in the first years of economic cooperation among CEMA-member countries. At that time practical experience (and possibilities) for the use of a variety of organizational forms of international economic relations, most of which dealt with foreign trade, were still lacking. The instruments and institutions of multilateral relations were insufficiently developed. The further quantitative and qualitative development of economic relations called for the broadening of multilateral relations as well. Simultaneously, the necessary prerequisites were being created for that purpose. It became clear that a number of problems could be resolved far more effectively on a multilateral rather than bilateral basis (some problems could not be resolved at all on the bilateral level). This applied, for example, to the formulation of the principles governing the setting of foreign trade prices within CEMA and the area of foreign currency relations. Cooperation among member countries in the area of standardization could have been undertaken, from the very beginning, and developed successfully on a multilateral basis alone. Therefore, the multilateral forms of cooperation in a given area largely earmarked the frameworks within which bilateral relations could develop and, at the same time, played a specific role in boosting them. Thus, for example, the multilateral payments system, which has been used by CEMA for over 15 years, has always encouraged the development of reciprical trade even though its bilateral nature is still strongly emphasized.

Increased comprehensiveness of cooperation in production and research is of major importance to CEMA countries. Despite some unsatisfactorily resolved and still difficult problems, multilateral relations have assumed a solid position within the organizational forms of relation among CEMA countries. The latter have acquired considerable experience and skill in using them properly and expediently, and in effectively linking them with bilateral economic cooperation forms.

To CEMA-member countries the problem of the place, role, and correlation between bilateral and multilateral forms is of particularly decisive and topical significance in the field of planning. The new and higher forms of cooperation in this area called for a basic revision of the ties and relations between the bilateral and multilateral forms. Problems in which all or most CEMA-member countries are interested can be effectively resolved on a long-term basis only following the drafting and adoption of the necessary measures and the consideration of the conditions and possibilities of all the countries. Multilateral decisions must be based on profound studies made by national planning organs, studies which would also contain optimum solutions for the implementation of joint initiatives. The conclusion, therefore, is that the extension of multilateral forms of international economic relations is closely linked with greater comprehensiveness, longer range, and higher levels of analytical preparations for cooperation in various areas.

The close ties between the bilateral and multilateral forms in planning become particularly clear in the joint pooling of enterprises and industrial projects. Currently, a number of projects have been built within which the CEMA-member countries have combined material, financial and mental resources, thus resolving important problems of supplies and of satisfying the national economies with raw materials, energy, and fuels. All these problems, such as the capacity of the industrial facilities under construction, important technical and technological parameters, problems of ownership, reciprocal applications, share of participation, and others, are discussed and resolved on a multilateral basis. On the basis of multilateral agreements (for the joint construction of the Ust'-Ilim Cellulose Combine on Soviet territory, undertaken by Bulgaria, the GDR, Poland, Romania, the USSR, and Hungary, the Kiyembaya Mining-Concentration Asbestos Combine, and a number of other projects), the countries sign bilateral agreements in which they stipulate the details of conditions and reciprocal obligations, such as the variety of goods to be supplied, supply terms, and others. It is thus that in a number of cases multilateral agreements are "refracted" into a number of bilateral relations and it is through them, actually, that they are implemented. In some cases bilateral agreement concluded separately by several CEMA-member countries with the Soviet Union in a certain area would require multilateral talks. This is necessary, for a bilateral relation alone would restrict the finding of the most effective long-term solutions.

The principles governing the bilateral and multilateral methods do not always appear in their pure, ideal aspect. They are not always clearly demarcated, for in a number of cases elements of either of the methods become interwoven with the other. Occasionally, contradictions arise between them in various areas of economic cooperation. The contradictions are mainly between form and content. They arise mainly in the case of insufficient maturity of multilateral relations in a given area where, in fact, they are developing on a bilateral basis, even though from the organizational-technical viewpoint they have assumed a multilateral form.

Bilateral and multilateral features apply both to the commodities area (foreign trade, specialization and cooperation, joint construction, and others) as well as the process of payments. Usually, bilateral relations in foreign economic relations correspond to bilateral forms of account settling. The multilateral organization of payments presumes logically developed forms of multilateral foreign economic relations. In some cases, however, the form of payment relations outstrips the development of economic relations. Relations in the commodity area, still based on the bilateral method, are pitted against the multilateral system governing foreign exchange operations among the countries. A similar picture prevails currently on the international socialist market in which economic relations among CEMA-member countries are characterized mostly by their bilateral nature, even though a multilateral system of payments has been established.

In foreign trade, under socialist conditions, the multilateral method is manifested, above all, in the planning, coordination, and balancing of

commodity deliveries by one country to all other countries put together, rather than separately to individual countries. The latter characterizes the bilateral nature of foreign trade relations. In multilateral trade the need is eliminated for the strictly bilateral balancing of imports and exports in terms of value and quantity. An important characteristic of the multilateral method of socialism is that it is achieved at the planning stage, within the framework of joint planning activities and the coordination of supplies, based on the implementation of the various forms of economic cooperation and on socialist economic integration.

At the same time, multilateral foreign trade consists of a number of bilateral relations, since each country establishes and maintains trade relations mainly on a bilateral basis. Multilateral foreign trade does not mean the elimination of such bilateral relations. It presumes the possibility and conditions for the planning and balancing of foreign trade on the basis of multilateral balancing and equalization.

As we know, currently multilateral foreign trade on the socialist market is virtually not applied for a variety of reasons, even though the necessary organizational and contractual forms for it have been developed: the two-step sequence in the development of trade talks, according to which the first step covers, in general, import and export deliveries without overall balancing, and the second step, which calls for the balancing of reciprocal deliveries on a multilateral basis.

Considered in the area of international foreign exchange relations, the multilateral method is a method of payments in which one country settles in full its foreign exchange obligations to other countries through foreign exchange income it has earned in those countries, with no restriction as to amounts and objectives. This way, the multilateral factor in this area is conceived as the unhindered use of the assets of a country in settling its obligations with the others. Multilateral foreign exchange relations follow the principle of global balancing of payments and income rather than the principle of bilateral balancing, which is known for and characterized by maintaining a strict balance between the assets and liabilities of the two countries for a specific time period.

Multilateral forms of payment began to be introduced in relations among CEMA-member countries at the beginning of the 1960s. Until then bilateral settlement of accounts was the basic principle in balancing foreign trade and payments. Bilateral trade agreements were the main organizational-contractual method used in foreign trade. They were long term, covering a five-year period, and annual protocols. In the area of international payments, they consisted of bilateral clearing agreements. The latter proved to be the most expedient form of payments relations among socialist countries at that stage in the development of their economic cooperation. As the economic potential of the socialist countries rose, and as new, more progressive and more effective forms of economic cooperation appeared on this basis, such as multilateral coordination of national economic plans,

production specialization and cooperation, joint production activities, and others, a strictly bilateral method in trade and payments could become a hindering factor in the development of a rational international socialist division of labor. The strict bilateral balancing of payments forced the countries to limit the size of their imports to that of their export possibilities. In other words, reciprocal trade was limited by smaller export possibilities of one of the two countries.[1]

The establishment of new forms of economic cooperation among the socialist countries, of specialization and cooperation above all, could have sharply clashed with foreign trade and payments systems. The prospects for further expansion and intensification of the international socialist division of labor on a multilateral basis called for a corresponding form of payment relations which would provide scope for and cooperate to a maximum extent in the implementation of new forms of economic cooperation.

Meeting these requirements and responding to the trend of further expansion of economic relations, of total utilization of potential specialization and cooperation possibilities, above all, the CEMA-member countries developed a system for insuring the conversion from bilateral to multilateral settlement of accounts, based on a transferable ruble. The principle of multilateral payments, on which the new system of payments was based, had as its main purpose the acceleration and expansion of reciprocal trade and the further development and intensification of the international socialist division of labor. The main intent of the 1963 agreement was to convert through the transferability of the collective currency from the bilateral to the multilateral balancing of payments and, on this basis, provide an impetus for the development of multilateral economic relations as well within CEMA. The main advantage of the multilateral system of payments, compared with bilateral clearing agreements, is, above all, that from the viewpoint of payments more favorable conditions are created for the expansion of international economic cooperation and for socialist economic integration. A comparison between the two methods of payment shows the main advantage of multilateral payments in terms of foreign trade: they create more advantageous prerequisites for the development of trade.

However, we must emphasize that the introduction of the transferable ruble as a monetary unit for multilateral payments could not immediately bring about an effective multilateral type of foreign trade and payment relations among socialist CEMA-member countries. Past experience shows that at the end of the year payments are balanced almost entirely between the respective pair of countries. This is due, above all, to the fact that the countries plan their foreign trade, which generates most of the payments, as a rule on the basis of a bilateral annual balance. Necessarily, it follows that payments between countries will be equalized on a bilateral basis. Such bilateral balancing was done by the countries on a deliberate and planned basis.

quality and value, adding to them secondary goods as well. In reality, commodities belonging to the second group are subject to additional contracting in the course of multilateral talks. The existing relative shortage of goods important to the national economies of the socialist countries is the main reason for some economists to speak of a certain bartering in trade and of the predominance of distribution functions in foreign trade.[2] The desire to achieve a strict balance in trading commodity groups of the same kind and the exchange of some raw materials for others or of some machinery for a specifically determined other type of machinery hinders the increase in the relative share of goods coordinated on a multilateral basis. Other factors, such as unjustified duplication in the production of individual commodities by several countries simultaneously, the lower quality standard and technical indicators of some export goods, substantially different from contemporary global standards and prototypes, and so on, adversely affect the multilateral aspect of foreign trade.

2. The organizational and contractual forms on which foreign trade, scientific and technical cooperation, crediting, and others are based also play a certain role in the desire to retain bilateral balancing, even though not a decisive one. Long-term agreements and trade protocols consider, as a rule, mainly the possibilities and interests of the respective pair of countries. In the course of over 25 years specific structures and export and import ratios have been able to develop in foreign trade relations among socialist countries, characterizing and distinguishing, from the quantitative and qualitative viewpoints, the trade operations of the individual countries. Until 1 January 1964 the bilateral trade agreements were consistent with the clearing payments system adopted by the countries. Following the introduction of the multilateral system of payments, bilateral trade agreements were retained as the main organizational-contractual foreign trade method. However, the need for strictly balancing supplies between two individual countries was eliminated.

3. Contradictions between the multilateral form of payments and the nature of economic relations among CEMA-member countries are created also as a result of the bilateral nature of the determination of contractual prices in reciprocal trade. We know that different prices prevail in trade relations between a given country and other countries for identical commodities. Even though minor, this price disparity encourages the countries to export more to other countries which pay higher prices and slow down their supplies to countries offering lower prices.

An important question to be answered is that of the extent of multilaterally planned and balanced payments among all partners within CEMA, so that full use could be made of the advantages of the multilateral system of payments in developing reciprocal trade and, respectively, the international socialist division of labor. In our view, in the future as well, a considerable share of reciprocal trade will be balanced bilaterally. The idea of developing the multilateral principle of balancing and equalizing in the area of foreign trade should hardly become a self-seeking aim. Overestimating this

Following the enactment of the multilateral system of payments in transferable rubles, from the foreign exchange viewpoint organizational-technical prerequisites were created which, by themselves, could not insure the development of multilateral trade and the intensification of multilateral cooperation. Indeed, the multilateral transferring of the transferable ruble could be achieved only through the combined effect of the following two factors: the creation of a system for multilateral utilization of the currency (a factor of organizational-technical nature); and development of economic relations on a truly multilateral basis (an economic factor). The latter factor is determinant. In this connection, we must answer the question of what it is that makes it incumbent upon the countries to plan their trade relations on the basis of an annual balance. In our view, the reasons may be found mainly in the material-production area. The essence of the problem would not be affected by reasons such as the bilateral forms of planning coordination, trade agreements, or contractual prices, even though as organizational forms they have a certain influence on bilateral balancing. The essential reasons are deeper: they are found in the material foundations which are the target of planned coordination, trade agreements and the price setting system. The extent to which reciprocal payments may be equalized bilaterally or multilaterally is, above all, less a problem of development of the transferable ruble than of its material foundations. The mechanism of multilateral payments is a necessary prerequisite from the foreign exchange viewpoint. From the economic viewpoint, however, it is insufficient for insuring the conversion to multilateral trade. In practice, prerequisites have been organized in a socialist market for the effect of the former factor without the full operation of the latter, determining factor. Consequently, the reason does not lie in the mechanism of payments but in economic interrelationships, including foreign trade which is continuing to develop essentially on a bilateral basis. This situation triggers contradictions between the multilateral method of payments and bilateral economic relations. The main contradiction appears in the desire of all countries to correlate precisely their sales with the counterpurchases of goods considered identically valuable in terms of quantity and value. Thus, the basic motivation in the conclusion of intergovernmental trade agreements is the bilateral balancing of trade. This conflicts with the multilateral mechanism of payments, which presumes the elimination of the precise bilateral balancing of imports against exports and, hence, of payments against earnings. The high share of reciprocal deliveries which continue to be coordinated on a bilateral basis may be explained by the effect of the following more important factors:

1. The lack of adequate export stocks of some basic commodities is an important economic reason for the underdevelopment of multilateral foreign trade. At the same time, however, there is a relative surplus of low quality goods, of unsuitable appearance and varieties which are not in demand. This leads to the classification of goods into those in greater or lesser demand or with no demand. This also explains the desire of the countries to link in the greatest detail, in terms of quality and technical indicators, the export of "strong" goods with the import of the same type of goods of equivalent

principle could lead to economically adverse consequences both for the individual countries and for the socialist economic comity as a whole. However great the efforts of the CEMA countries might be to intensify the multilateral forms of economic cooperation and, specifically, of foreign trade, they face precisely defined limits. Beyond such limits they find bilateral balancing which can be neither belittled nor ignored. Conversely, in a number of cases it must be developed, intensified, and improved, for it is a decisive factor in economic relations among countries. Thus, for example, trade with the Soviet Union accounts for nearly 50 percent of our country's overall trade. There could be no question here of radically restructuring the bilateral principle governing the planning, balancing, and equalizing of trade between these two countries. This concept is further emphasized by taking into consideration the course charted by our country of comprehensive rapprochement with the Soviet Union. The same applies to the economic relations of the other CEMA-member countries with the Soviet Union. Meanwhile, new ways and means are being sought for purposes of introducing various elements of multilateral relations which would help and boost their relations with the Soviet Union and among themselves. In this light the existence of multilateral forms in the area of industrial cooperation and regulation of trade on a bilateral basis cannot be considered a shortcoming or a contradiction. A large share of the goods in whose production our country has specialized will continue to be handled on the basis of our bilateral relations with the USSR. In our view, this is a normal process. A bilateral balance of payments based on this fact should not be considered a negative phenomenon. Only a situation in which bilateral relations would restrict trade and other forms of economic cooperation could be considered negative. The volume of the controlled balances between the two countries will be determined, above all, by the export possibilities and structures of the two countries and the state of the balance of payments of each country in transferable rubles. It would be difficult to set any kind of quantitative optimum as to the share of the multilateral equalization of payments. The following formulation could be applied in the most general terms: the share of multilateral payments should be such as to stimulate, to a maximum extent, the expansion of trade and the international socialist division of labor. It is a question here not of eliminating the bilateral nature of coordination, trade agreements, or setting of contract prices, but of the drafting of new supplementing instruments in accordance with established material conditions and the qualitatively new requirements arising on this basis.

The CEMA-member countries face exceptionally important problems which must be resolved in order to implement the comprehensive program, related to production specialization and cooperation, scientific and technical cooperation, and development of multilateral foreign trade. The development and solution of foreign exchange problems, whose main element is the even more effective application and improvement of the system of multilateral payments in transferable rubles, will greatly help in the effort to attain these objectives. In turn, this is related to improving the entire system of economic cooperation and of its mechanism, for foreign exchange relations

are the product of cooperation in material production. In order for all the advantages of the multilateral system of payments to be fully used, a number of factors must operate in the fields of management, planning, material-production, foreign trade, and foreign exchange. A really multilateral method may not be achieved in payment relations among CEMA-member countries separately or without the presence or creation of the necessary prerequisites in a number of other areas of economic life and cooperation among CEMA-member countries.[3] In this respect a convincing statement was made by Czechoslovak economist Ch. Konecni: "Replacing bilateral with multilateral principles is not a question of simply a wish or decision to follow one or another line."[4] Such a substitution could be achieved only on the basis of corresponding economic and organizational prerequisites.[5] Such prerequisites should be created through comprehensive measures not only in the foreign exchange area but, above all, in the area of material production, foreign trade, planning, and other fields of multilateral cooperation.

A study of the problems related to the development of foreign economic relations and of payments among countries, arising on their basis, shows the subordinate position of foreign exchange-financial relations within the overall set of economic relations. It indicates that in the conditions of the global socialist market the problem of multilateral payments is a function of the nature of economic relations in the material-production and foreign trade areas and that it cannot be resolved through foreign exchange instruments alone. This leads us to the search for and discovery of conditions, prerequisites, and means for achieving a multilateral type of payments not one-sidedly but comprehensively and all-embracingly. The main ways and prerequisites in this direction could be classified as follows:

Conversion to forms of multilateral coordination and national economic plans among CEMA-member countries;

intensification of international specialization and cooperation;

conversion to forms of multilateral balancing of trade and improving its organizational forms;

improving the system of payments and credits.

All this leads to the conclusion that the implementation of the decisions included in a comprehensive program, aimed at developing a multilateral system of payments among CEMA-member countries, calls for the creation of comprehensive conditions and prerequisites at the respective stage in the development of socialist economic integration.

FOOTNOTES

1. At the end of the 1940s and beginning of the 1950s the socialist countries used the simplest multilateral methods for settling reciprocal payments: trilateral single transfers of balances from one clearing account to another.

PROPER UTILIZATION OF AVAILABLE ARABLE LAND SURVEYED

Sofia PLANOVO STOPANSTVO in Bulgarian No 6, 1980 pp 18-26

[Article by Evgeni Petrov, senior scientific associate first class, candidate of economic sciences: "Basic Directions for Improving the Utilization and Preservation of the Land"]

[Text] Our country's agriculture is faced with important tasks: increasing the volume of agricultural output in order to meet steadily growing needs and upgrading production effectiveness. The successful solution of these problems depends on the extent of the utilization of land resources and the measures taken for the latter's preservation and reproduction. That is why the BCF Central Committee and the government are paying special attention to the land. As a result of this the output and income per unit of area have been rising steadily. Between 1977 and 1978, compared with 1960-1961, overall output per unit arable land, computed on the basis of comparable 1971 prices, rose by a 2.7 factor while net production rose by a factor of 2.4.*

Production rose as follows: grain, 73 percent; fruits, 70 percent; meat, 14 percent; milk, 65 percent, and so on.

The land resources in the country are divided into three land funds: agricultural (covering 61.9 percent), forests (34.6 percent) and settlements (3.5 percent). The agricultural fund accounts for 97 percent of the pastures; the forest fund accounts for 98.9 percent of the forests and 3 percent of the pastures; the settlements contain the virtually entire built-up area as well as 2.8 percent of the country's arable land.

The bulk of the land, the fertile land mainly, is used for agricultural production. Consequently, the extent of its utilization also determines, in its essential lines, the extent of the management of the country's land resources.

---

* All data used in this article come from the 1977 and 1978 statistical yearbooks of the Bulgarian People's Republic and the annual reports of APK [Agroindustrial Complexes].

The basic direction in upgrading the utilization of land resources in agriculture is the steady upgrading of production intensification. Compared with 1960, in 1978 productive capital per unit of arable land rose by a 3.5 factor while production expenditures rose by a factor of 2.3.

Intensification is developing at a fast pace in all directions. New strains of various farm crops are being applied continually. The number of tractors, in terms of 15 hp per 1,000 decares of arable land, has increased by a 4.2 factor; power supply has increased by a factor of 3.2 and chemical fertilizers by a factor of 4.3. The share of irrigated areas of the entire arable land has risen from 14.2 percent to 24.2 percent. As a result, the level of agricultural intensification has risen significantly. Currently it is close to that of the developed countries. Productive capital per decare of arable land has risen to 140 leva while production expenditures have reached 90 leva (Table 1).

Table 1. Growth of Agricultural Production Intensification

Indicators	1960	1965	1970	1978
1. Production costs per decare arable land in leva	38	47	62	88
2. Productive capital per decare arable land in leva	40	63	91	139
3. Tractors in terms of 15 hp per 1,000 decares arable land, number	0.8	1.4	1.9	3.4
4. Power supply per 1,000 decares arable land in hp	66.0	100.6	163.6	210.4
5. Chemical fertilizers in terms of active substance per decare arable land in kilograms	3.2	7.5	13.3	13.8
6. Share of irrigated areas of the total arable land in percent	14.2	18.9	21.0	24.2

Compared with the output before the socialist reorganization of agriculture, farm yields have risen by a 2.3 factor (Table 2).

Despite successes achieved in agricultural production intensification, it will remain the basic direction to be followed in improving the utilization of the land. This is necessitated by the limited size of the arable land and the reduced possibilities to increase it, as well as because of the great potential possibilities offered by the now applied individual crop strains.

In order to upgrade soil fertility, the use of chemical fertilizers and irrigation must be increased in the future. Furthermore, we must continue to introduce new highly productive and better quality strains, expand mechanization in labor intensive sectors (vegetables, tobaccos, perennials and others), and apply industrial production technologies.

At the present stage particular attention is being paid to upgrading the quality and utilization of productive capital, including that which is directly related to the utilization of the land.

Natural conditions and, more precisely, soils and solar heat, enable the country to grow a large number of highly intensive crops. The growing of steady high yields is largely determined by the amount of precipitation which may be insufficient and unevenly distributed throughout the year. That is why irrigation is one of the most important factors in improving land utilization.

Our country has built big irrigation systems. Capital investments for irrigation have exceeded 1.5 billion leva. Irrigated areas total 11.3 million decares. However, only about 82 percent of them are actually irrigated. Crop yields from such lands are frequently below their potential possibilities for the following basic reasons: insufficient water supplies, low technical standard (76.8 percent are irrigated gravitationally), insufficient spraying equipment, low effectiveness of the network of canals, and others. Consequently, labor productivitiy in irrigation is low (11 decares per man/shift). A great deal of water is lost (0.50-0.60 efficiency) and the watering regime of the crops is frequently violated, which adversely affects yields. That is why one of the basic tasks facing agriculture is the reconstruction and modernization of irrigation systems with a view to upgrading labor productivity and insuring the maximum utilization of the water and the land in order

to increase agricultural output. Furthermore, the building of new irrigated areas must be continued. Studies have indicated that as many as 36 million decares, or 60 percent of the farmland, could be irrigated. Should such irrigated areas be developed, the volume of agricultural output could be increased by more than 30 percent as a result of irrigation alone. This, however, requires substantial additional capital investments.

Perennials account for 7.2 percent of the arable land in the country. Their yields remain inadequate. This is due to the strains used, type of fertilizer, irrigation, technology, and others. The share of non-fruit-yielding perennials remains high. This lowers the volume of output. That is why the reconstruction of some of the land in perennial crops and upgrading intensification are currently an important reserve for the better utilization of the land.

As a result of the major changes which have taken place in the structure of the national economy and increased mechanization, the size of the manpower in agriculture has been reduced considerably. The process is continuing. However, the size of the manpower is declining faster than mechanization is increasing in a number of basic agricultural subsectors (truck gardening, tobacco, perennials). This is having an adverse effect on these crops. Increased mechanization of labor intensive crops is a necessity both in terms of upgrading labor productivity and improving the utilization of the land.

Another main direction to be followed in the utilization of the land is to improve the structure and territorial location of agricultural production.

As we pointed out, natural conditions in our country make the production of a large number of crops possible. We know that the individual crops have different potentials in terms of investments and labor and, on this basis, growing greater quantities and increasing the income per unit area. Improving the utilization of the land calls for the utilization of all opportunities for expanding areas planted in more intensive crops. Accordingly, the country has been pursuing a systematic policy of increasing the share of such crops. Over the past 20 years areas planted in sugar beets, tobacco, vegetables, and perennials have been expanded considerably while areas in grain crops, wheat in particualr, have been reduced. We must note, however, that even though suitable areas for growing such intensive crops still exist, available manpower resources and the need for substantial additional capital investments will not make substantial structural changes possible over the next few years.

The great variety of natural and economic conditions prevailing in the different parts of the country also make the problem of the territorial location of agricultural production particularly important. Growing

individual crops under the most favorable conditions has a decisive influence on their effectiveness. That is why great attention is being paid to this problem. Respective studies have been made and a chart for the zoning of basic crops and types of livestock have been drafted. In this respect, particularly after the organization of agroindustrial complexes in the country, starting with 1971 a systematic policy has been pursued of decisively improving the territorial location of production facilities. Areas have been specialized in the growing of grapes, apples, sugar beets, and so on. The process has not been completed. In our view, it must be accelerated by paying greater attention to crops whose requirements in terms of natural conditions and the production structure of irrigated areas are greater and specific. All opportunities must be used to increase the share of more intensive and moisture-loving crops on irrigated areas. This would not only improve land and water management but would make it economically expedient to increase capital investments per unit area so that we may convert from gravitational irrigation to spraying and other more productive yet also far more capital intensive irrigation systems.

Packing the cultivated area with the help of secondary and intermediate crops is an important reserve in upgrading the utilization of the arable land. Natural conditions and, particularly, the extension of irrigated areas make it possible to raise as second crops, following the wheat and early spring crops corn for fodder, late vegetables, tobacco, and others and, before the late spring crops, winter vetch, winter peas, mixed vetch and pea crops, some vegetables, turnips, and others. Our country has acquired rich experience in this area. Let us emphasize that this possibility is being underestimated in many respects. In the country at large these crops account for no more than 10 to 12 percent of the cultivated area compared with a possible 15 to 18 percent, and, in the case of irrigated land, up to 25-30 percent. Naturally, the size of such areas largely depends on weather conditions throughout the year, for in some cases such conditions are adverse and result in losses rather than advantages.

Our country has extensive natural pastureland (26 percent of the farmland). This land, however, is used extensively. It is virtually not fertilized or irrigated. The grass structure has worsened. Yields range between 300 and 500 kilograms of green mass per decare. The better utilization of such land presents agriculture with a major problem. For this reason, in recent years the development of grazing complexes has been undertaken. They could resolve all problems related to improving the condition and utilization of pastures: clearing of rocks and bushes, planting grass, fertilizing, road construction, building livestock and residential premises, developing water supplies and others. This would enable us to considerably improve the utilization of such land and double or triple grass yields. In many cases such grass could yield hay as

well. This would create better conditions for the development of sheep breeding and, partially, cattle raising.

The preservation and improvement of land resources is an important topical problem. Let us note, above all, that the share of the land used (arable, pastures, and forests) is low--89.6 percent. Arable land accounts for no more than 42.8 percent. This is due to the predominantly hilly, semimountainous, and mountainous topography.

Not only is the share of the arable land small but it is steadily declining. Between 1960 and 1977 alone it declined by 1,423,000 decares, or 2.9 percent. Every year an average of 83,700 decares are lost to cultivation.

The reduction in the size of the arable land is due to two reasons: allocating land for construction and abandonment of unproductive land.

Every year as many as 50,000 decares are set aside for construction needs. This is the result not only of the extensive amount of construction taking place in the country but the increased norms of the necessary area for individual projects and the desire to build on areas close to settlements, transport arteries, and water sources. This leads to the loss of extensive farmland. Proper measures have been taken to improve control over this process. The National Assembly passed a special law on the preservation of the arable land and pastures. Special rates of payment for such land were introduced, ranging, according to the category of the land, from 400 to 40,000 leva per decare. The construction workers were ordered to preserve the humus of the soil in some areas in the course of earth removal operations. After the exhaustion of open pit mines and quarries, the areas must be rebuilt and become useable for crop growing. Land may be appropriated only by decision of the Council of Ministers.

As the result of these measures, in recent years the amount of land allocated for construction declined considerably. In 1977-1978 it averaged 22,000 decares annually.

The second reason--removing from the arable land fund the underproductive land--is caused by the poor condition of a considerable percentage of this land. Because of the rugged topography and age-old human activities, a high percentage of farmland is subjected to water erosion. About 10 percent of the farmland has become severely eroded.

In 1975 there were 1,848,000 decares of abandoned land; in 1978 the figure was reduced to 1,285,000 decares as a result of the measures taken. Furthermore, as a result of river flooding, construction, or organizational and other reasons, every year about 350,000 to 450,000 decares of arable land remain unused. In other words, about 96 percent of the arable land is actually used.

Our country is applying reclamation and other measures to resolve the problem of the preservation and fuller utilization of the land. All okrugs have set up specialized enterprises in charge of reclamation and other measures for the struggle against soil erosion, land recultivation, draining, clearing, and others. All such measures are financed from a special state budget fund. Practical experience has indicated that this is a successful method for the preservation of the farmland. Furthermore, antierosion measures are being implemented in forest land, most of which consists of sloped and eroded areas.

It is worth noting that periodically, in recent years in particular, extensive wind erosion as well appeared in northern Bulgaria. A considerable share of the soil in some sectors was carried away and crops were destroyed. This is due not only to the strong wind but the system of land management, particularly of open and highly crumbling soil, in the spring. So far, however, no particular measures have been taken in this respect even though the need for them is extremely urgent.

Currently our country is formulating a long-term program for the struggle against water and wind erosion. It covers all land resources. The plan calls for the simultaneous formulation and implementation of all antierosion measures in the individual water basins. The implementation of this program will limit erosion processes to a maximum and will improve the condition and insure the more rational utilization of the land.

Upgrading the fertility of soils which are excessively moist on the surface, acidic, and saline is of great importance to the better management of the farmland.

The country has about four million decares of land which is excessively moist on the surface. This is fertile land with heavy soils and a shallow layer of clay, or else land located near rivers with natural seepage. During periods of heavier precipitation they retain the water while in drought periods some of them are short of ground water. As a result, the crops cannot be planted on time and either require moisture or suffer from a great shortage of moisture. Crop yields on such lands are 20 to 30 percent lower than average and no crops could be planted at all on some of them which must be used as meadows and pasture grounds. In order to improve such soils they must be drained and the plowed stratum must be deepened. Even though essentially the necessary measures to be applied are known, so far nothing has been done to insure the improvement of such lands.

A similar situation prevails with acid soils which total 1,750,000 decares, and with 250,000 decares in salinized soils. The nonutilization of such areas causes the national economy annual losses in excess of 150 million leva.

Preservation from pollution is of major importance for the land in our country. As a result of the development of industry, transportation, and other activities about 550,000 decares of farmland have already become polluted. The main polluters are the cement, metallurgical, chemical, and other plants and the thermoelectric power plants. Decisive, yet still insufficient, measures have been taken in recent years to stop such pollution. With a view to improving work in this respect, in our view, it would be expedient to impose stricter penalties on enterprises which pollute the land, demanding of them to pay for the losses suffered from the worsening of soil fertility and the lowering of yields and of the quality of output.

Every year new land is being developed, even though in small amounts, to compensate for the reduction in the size of the arable land. The basic sources here are the elimination of forests, the plowing of natural pastureland, the draining of swamp land, and the recultivation of areas affected by industry and construction. However, the possibilities in this respect have not been entirely exhausted. In recent years we have been developing an average of 10,000 to 27,000 decares. We still have substantial areas which could be recultivated and drained. A particularly major problem is that of engaging in a more decisive conversion of unsuitable arable land which could be used for the planting of forests and grass, while flat and fertile land currently covered by neglected forests, natural pastures, and others could be developed for farming. This would enable us to stop reducing the size of the arable land, which is an important national problem.

The studies we have conducted on the reduction and increase of arable land indicate that real possibilities exist for the expedient transformation of some soils and for limiting the reduction of the size of the arable land (Table 3).

Table 3. Changes in the Size of the Arable Land From 1980 to 1990

Indicator	Area, Thousand decares
I. Reduction	589
1. High construction	85
2. Highways and railroad tracks	14
3. Dams and Canals	68
4. Mines and quarries	71
5. Corrections of rivers and ravines	6
6. Forestation	177
7. Natural pastures	168

[Table 3, continued]

II. Expansion	751
1. Natural pastures	312
2. Forests	297
3. Swamp draining	48
4. Recultivation of unused land	82
5. Irrigation canals	12
Difference	62

The main idea of the suggested transformation is to plant grass on about 168,000 decares of eroded and abandoned underproductive land and plant trees on 177,000 decares. Conversely, 312,000 decares in pastures and 297,000 decares in forests will be plowed under. This is a minimum amount. Greater possibilities exist for the development of arable land currently in forest resources. However, this should be done gradually following the planting of new forests.

The government's decision to distribute for use by the population some of the abandoned underproductive arable land plays a great role in limiting the reduction in the size of the arable land. So far about 450,000 decares have been distributed. In no more than some 2 years a certain percentage of this land has been radically improved: It has been cleared, terraced, and cultivated. Currently it is used for the production of fodder, fruits, and other valuable farm crops. All this indicates that considerable successes have been achieved and important measures are being implemented to improve the utilization and preservation of the country's land resources. Still, a number of problems must be resolved thus providing real possibilities for the fuller utilization and preservation of land resources. This includes the protection of soil fertility of about 15 million decares threatened by erosion and pollution, flooding, and destruction from construction, and of about 6 million decares of overmoist, acidic, and salinized soils. Corresponding programs have been formulated for the solution of such problems: A national program for the struggle against erosion, a program for upgrading the fertility of 15 million decares, and a program for improving the condition of and developing pastureland complexes covering 4 million decares of natural grazing land.

The implementation of such programs will require capital investments in the hundreds of millions of leva. In our view, this circumstance requires the preliminary clarification of several basic problems.

First, we must determine the ratio which must exist between the engineering-technical and agrotechnical measures aimed at the preservation and

upgrading the fertility of the soil. In a number of cases agrotechnical measures are equally effective and require lesser capital investments, for which reason they are preferable. Such is the case, for example, in the struggle against soil erosion, improving some overmoist soils, and others.

Second, let us note that technologies for the improvement and preservation of individual soils have not been developed in the necessary detail, or else that measures have been suggested whose practical effectiveness has not been proved.

Third, we must increase the availability of specialized equipment for the preservation, improvement, and work of such lands, along with the necessary fertilizers, lime, gypsum, and other means.

Fourth, let us note that our country has a specialized organization in charge of planning measures and well-trained specialists in this area.

Fifth, systematic studies are not being conducted by the complex groups and expeditions studying the condition of land resources in the country for purposes of suggesting specific measures. The National Agroindustrial Union does not have a standard manual on this important problem.

All this indicates the need for the creation of a better organization and for expanding the study, planning and, particularly, the implementation of measures related to the transformation, preservation and improvement of the utilization of land resources in the country. For the time being adequate possibilities exist in this respect. However, they must be used most expediently.

TIGHTER CONTRACTUAL DISCIPLINE DEMANDED BY MINISTRY OF METALLURGY

Budapest MAGYAR HIRLAP in Hungarian 29 Jul 80 p 6

[Article by N. B.: "On Contractual Discipline"]

> [Text] Recently there appeared a document which sets forth the most important directives in contractual discipline for the sake of the metallurgical and machine industry enterprises. We asked the Ministry of Metallurgical and Machine Industries for information on the purpose of the directives and their new features.

Nowadays the frequent irregularities in contacts between enterprises are called "contractual lack of discipline," on the model of the expression "contractual discipline." Frequently enterprise cooperation is not adequate, and in quite a number of enterprises a contract is only a formality. They often fulfill their obligations late, quality is below the enterprise capability and deliveries are irregular. Breach of contract brings practically no consequences, and enterprises frequently reject justifiable penalties and indemnities.

In the Interest of the Small Consumer

One of the most important purposes of the new directives is to reform enterprise behavior. Thus one result will be that enterprises will respond concretely to orders and solicitations. At present there is the practise of merely stating the possibility of concluding a contract, instead of giving the time and other details. This, for example, seriously damages the availability of goods. Another equally important point in the document is that in the future the interests of the small consumer must not be pushed into the background.

The KGM [Ministry of Metallurgical and Machine Industries] is also proposing to the enterprises that they live more frequently with the idea of preliminary contracts. From a number of points of view preliminary

contracts are advantageous: they help establish long-term economic ties between enterprises and, among other things, they imply adequate bonds on the legal side, in opposition to possible "disappearance" into the industrial background.

On the basis of experience the KGM powers have determined that some of the enterprises do not do enough for the contracts they have made, and in general do not include contractual obligations in their basic tasks. In this connection the document prescribes that contracts must be fulfilled by the appointed date, at the rate decided on and according to the conditions accepted. If any unforeseen situation interferes with this, it is the duty of the consignor to inform the purchaser of the situation in good time.

It is a well-known fact that when enterprises set up their manufacturing schedules, they often cause each other trouble. For example, one firm will plan to export complete assemblies, and in the meantime its partner will drop the production of an electric motor planned for incorporation into the assemblies, or of some other product. According to the directives, it is absolutely necessary for producers to fulfill their accepted obligations, on the basis of pertinent decisions, if they plan to eliminate the manufacture of some products.

The weakest point in the current contractual system is the validation of demands resulting from breach of contract. If a basic charge is justified at all, this is certainly the place. The document particularly calls attention to two essential viewpoints. One is that, although the legal measure refers the decision of validating a demand for a penalty in favor of the wronged party to the competent jurisdiction, it is impossible to understand how the enterprise cannot be obliged to consider the circumstances of breach of contract. In every case it is necessary to examine the real harm done by breach of contract. Another new element is that an economic penalty can be levied on the basis of a government decision of last year, if an enterprise regularly manufactures products of poor quality, if it repeatedly insists on contractual conditions favorable to one party and if there are a number of cases of its not honoring demands caused by having failed to fulfill a contract.

Lack of Internal Organization

According to the KGM authorities the legal and economic work of the enterprises must be continuously improved for the sake of the contractual system. Let us observe that in general the lack of internal organization also works against the fulfilment of contracts. The establishment of contacts between enterprises is inseparable from the organizational level within the enterprise.

PLIGHT OF DISADVANTAGED COOPERATIVES WORSENED BY SPECIALISTS

Budapest MAGYAR HIRLAP in Hungarian 29 Jul 80 p 3

[Article by Nandor Keresztenyi: "Indifference"]

[Text] Recently I was able to witness a meeting where the refrain could have been: "Kick a poor man while he's down." Forty chairmen of agricultural cooperatives, not known for their intelligence, presented a picture of their worries. This conference was well-suited to be a day of grievances, since various kinds of management handicaps lay a double burden on these cooperatives, the majority of which fit right in on the path of stragglers.

The repeatedly unbending strictness of the economic measures levies a double burden when the state tries to obviate poor production situations. However, even with pertinent subsidies it cannot reach the same level as previously, and those escaping the "protected circle" are now complaining of this fact, which may also be considered encouraging in itself, since this escape is nothing but a recognition of our economic level.

These and similar paradoxes would be widespread if they provided any information. However, instead of them, let me mention only a single grievance! "What I fear most is the indifference of some specialists, felt here and there, but more and more," said one of the chairmen, stating that the specialists orient one another to different places and methods: here in the megye plant protection station, there in the center of one of the plant production systems, and yonder to a new position somewhere else. "When I wanted to keep one of them at any price, it turned out that I was not in an equitable position, because he was offered more than my chairman's salary," the chairman reflected as he brought up this event, by no means unique.

Let me immediately add that the position of this chairman is not an exceptional one. Just recently I was talking with two chairmen who want to get away. For example, one of them considers himself capable of some kind of environmental protection work.... But let's not talk ironically. Indifference, negligence, is really a sign which we had better heed more than

more than any kind of changes in any economic regulator! This is an unfortunate psychological factor associated with the factor of an unfavorable production site. There is no longer any doubt that rehabilitation of an otherwise incompetent enterprise can have a number of brakes applied to expanded production.

From time to time the ageless subject of the participation of questionable areas comes up. What is this all about? According to a previous study by the Agrarian Economic Research Institute, 83 percent of the cooperatives in question can be found in ten of the country's megyes, while only 17 percent can be found in the other nine megyes. The main areas involved are: Orseg, the Zala hill region, the mountainous area beyond the Danube (Bakony, Vertes) Zselicseg, the Somogy hill area, the eastern mountainous area, Hegykoz, the sandy soil between the Danube and the Tisza, the Alfold plain and the Szabolcs-Szatmar sandy soil area. A document recently compiled by a major cooperative department in the Ministry of Agriculture and Food Administration revealed that 283 of the country's 1339 production enterprises have unfavorable facts and figures. Szabolcs-Szatmar has 70 such in 127 cooperatives, Borsod 39 in 107 cooperatives, Somogy 27 in 82 in joint economy, Zala 20 out of 24 and so on.

The relevant situation in Borsod, Heves and Nograd was discussed in quite a bit of detail and the Ministry personnel, among others, stated that there are chairmen who do not like to take on specialists with a diploma, but on the other hand it is also a fact that the university graduates have no desire to be associated with their poor accomplishments either. This is quite true. I have already seen chairmen who hid and closed professional periodicals fromehead agrarians with a diploma. If there is a reason for discouragement, this fact, trifling only in appearance, is one of them.

However, a definite counteroffensive is developing within the science. For it is not difficult to detect that the best antidote to a desire to go elsewhere can be summarized in funds. Last year the state supplemented the wages of 2,400 specialists with no less than 40 million forints, a form of support which can be maintained. There is also a proposal for reclassification, which again is not a new idea. Let us just think of the erstwhile order 3004 or the host of state farms and professional men "deposited" by the Ministry on the basis of this order, of whom more than a few helped strengthen the cooperatives between 1960-1970.

So, let a new order, numbered or unnumbered, come. If we are provided with anything, let it be orders. At any rate various well-accepted actions and relief could be begun to eliminate the indifference toward these common interests of ours. At the conference mentioned in the beginning, the fact that cooperative managers have been able to buy automobiles to the detriment of the state enterprises was brought up. What need is there of such differentiation, of any kind of differentiation? Following the example of some cooperatives which have moved forward from the ranks of the stragglers, it is possible to judge the scope of their role in the construction of official quarters, so why should this proven system not be accelerated and broadened?

I know that money is necessary in addition to resolutions, and not just a little. However, it is necessary to see that it is really spent directly on the proper purposes, which is economy. This is the way to at least partially eliminate the losses for which the state, in the final analysis, pays several hundreds of millions of forints annually.

MAINTENANCE OF HOSPITAL EQUIPMENT SHUNNED BY ENGINEERS

Budapest MAGYAR HIRLAP in Hungarian 29 Jul 80 p 5

[Article by Laszlo Fay: "Healing Engineers; Train Yes, Use No?"]

[Text] At present the value of the Hungarian stock of medical instruments is approximately 6 million forints. Some 25 percent of this is unusable or bad. An annual total of 20-30 percent of the industrial engineers, trained at a cost of 100,000-150,000 forints each to implement and repair the technical medical equipment, finds employment in the health service.

These data were presented at a specialized conference ten days ago before the lift-off of the first Hungarian cosmonaut. On the basis of our health plans, worthy of recognition on a worldwide scale, health service has advanced to a mass supply condition. However, service of such a nature requires a greater degree of automation, more and better equipment, and specialists of suitable training and in necessary numbers. Let us take a look at the men we can call medical-technical specialists in the contemporary sense.

Indispensable Collaborators

In the general view today these basically trained technical workers are considered to be in the group whose work is involved with healing or assists it in some way. A well-functioning hospital can be boldly compared to a factory operating according to a strict technological order. Here are found the same general supply areas (sanitary engineering, power, TMI [Preventive Maintenance]) and the so-called hotel services (kitchen, laundry) as everywhere else, and they do not demand any special health knowledge. On the other hand, because of the technical development in the last decade, the employment of a competent technical staff is a more and more urgent task. Specialists are needed who know how to implement, maintain and repair modern health equipment, devices, and apparatus and special instruments at a proper level. The healing teams, of which an indispensable member is the technical worker who takes an active part in the technological

operation of the hospital, are in development. Today in many developed countries it is already impossible to perform certain operations without the presence of the hospital engineers. Prevention, as opposed to healing, is playing a greater and greater role in the everyday activity of physicians, so it is easy to understand the importance of proper maintenance and reliability of the equipment to obviate random repairs. We are emphasizing their importance because the attitude has not prevailed everywhere yet that the presence of technicians is indispensable for providing high-grade health service.

An interesting matter is the training received by medical technical specialists. Naturally a pertinent differentiation is necessary here, since today both trained workers and certified engineers can be found in health service. When we speak of the level of training, we can in general distinguish three levels: certified engineers, industrial engineers and technicians.

Of these three groups the Kando Kalman Technical Electrical Institute seems appropriate only for the graduate training of industrial engineers. If certified engineers want to specialize in this area, they can simply acquire the desired information in special engineering postgraduate education, and since such postgraduate training is a matter of the budget, the number of participants is limited. The greatest concern is for those in the third class. Technician training disappeared from Hungary more than 10 years ago and the technician-quality system, which has taken its place, has received and is receiving a great deal of justified criticism. While this last problem requires a general solution, it is not a question of special medical technology, and still this is where the least development can be found: the shortage of medium-trained specialists is extremely perceptible in health service.

It is possible to establish all kinds of educational needs on the basis of an exact recognition of requirements, and this is the point where the opinions of interested parties diverge. In the past the educational leaders waited for a solution from the competitive system. However, they have had to realize that, as long as the enterprises are not obliged to fill the written competition places, they will ask for an unjustifiable number of engineers and afterwards make a selection based on their own approval. Thus the competitive system does not provide a reliable base for fulfilment of the requirements. (Presumably the enterprises would determine their needs more precisely if, for example, they paid the training expenses of engineers, instead of the central budget!).

We can get approximately exact data on the anticipated demands if we begin with the 6 billion forints worth of instruments mentioned above. In line with the method adopted in international practise, 10 million forints per specialist, it seems that 600 persons are required, but this is far from the approximately 300 medical-technical staff currently employed in health service.

There may be a mistake in the figures, but it is clear that in both cases the needs considerably outdistance the current staff, while we are not even mentioning industrial demands for 200-300 persons and the need to expand the personnel awaited in both areas.

What is the cause of the migration? How can it be that there are scarcely 40 workers in the health area and 40 in the medical-technical industry out of the 200 industrial engineers trained in this specialty at the Kando Institute during the past 10 years?

The Causes of Migration

At the conference mentioned above, the representative of the Ministry of Health spoke of a shortage of 50-80 technical experts on the highest level and 100-150 on the intermediate level, while at the same time a radio report stated that this year the health service advertised a total of three positions to be filled by new graduates.

These contradictions can be the result of inaccuracies in estimates, organizational questions or, most probable, personnel problems. It seems as if the health service authorities do not feel this situation themselves, and somehow view these events from the outside. In Hungary there has never been a census of medical-technical engineers or of industrial engineers. The majority of hospital and healing institutions do not know about this form of training, and therefore cannot demand such specialists. This lack of orientation and enlightening information can lead to millions being tied up in a shortage of components or, what is even worse, in a lack of proper maintenance and data processing.

More and more physicians are incapable of dealing with the technology and of acquiring the technical knowledge, if they did want to use the modern equipment entrusted to them. It is long since time for technical knowledge to be included in the training of physicians, and especially in refresher training. But when we speak of the technical training of physicians, we must not forget that their main mission is healing.

The Big Question

Thus the main question is not one of recent origin. We must accept the fact that the task of healing is a team task, under the guidance of a physician, and that the technicians in this group of workers are just as necessary as the representatives of other branches of science. Concrete institutions are necessary for this purpose, in addition to the readiness of every participant, since an enormous amount of energy has been lost in the past 10 years as a result of the lack of harmony, although most of the information acquired has been generally known.

The establishment of an interdepartmental committee, familiar with the difficulties caused by the divergence of the medical system in two special

directions (ministry, councillors) could lead to a solution by involving all interested parties (education, industry and others). The Medical-Technical Specialty Division of MATE [Scientific Association on Measures and Automation], which perhaps feels the problem most keenly, put this matter on the agenda of an international conference as early as 1972. Within the scope of the recommendations adopted there, the BME [Technical University of Budapest] implemented the training of engineers with diplomas in 1978, and the Kando Institute did so in 1979.

In the recent past we awere able to watch the program entitled "Palyakorrekcio" [Course Correction] on television. In it two young men discussed the results of uniting the studies taken at medical and technical universities. One of them, already a physician, was a student at the Technical University, and the other was in his last year at the Technical University when he was able to realize the great dream of his life and became a student at the Medical University.

These were naturally subjective decisions, but the effect of the social environment can be seen in their motivation. Would this be the solution?

POLICY AIMS AT CONTINUED INCREASE IN STANDARD OF LIVING

Plans for 1981-1985 Period

Bucharest REVISTA ECONOMICA in Romanian No 34, 22 Aug 80 pp 9-10

/Article by Dumitru Pugna: "Continual Growth of the Well-Being of the Whole Populace--the Supreme Goal of the Party's Policy"/

/Text/ Thirty six years of new history, each year bringing with it new and graphic proof of the continual progress of our society. The development of the production forces, their balanced distribution over the territory, the modernization of the structures of the economy, high rates of economic growth, among the highest recorded on a world level, and substantial increases in labor productivity in all sectors--these are some of the most significant elements for characterizing the country's economic and social development, the realism and scientific character of the view that lies at the basis of this development. The anniversary of the memorable historic act on 23 August 1944 constitutes an occasion for also bringing up other significant achievements, those obtained on the plane of well-being, of spiritual development. Because everything that is created on the land of Romania pursues, as the secretary general of the party, Comrade Nicolae Ceausescu, pointed out in the speech given recently at the grand people's assembly in the municipality of Braila, "the general development of the country, the raising of the well-being of the whole populace--the supreme goal of the party's policy, the essence of the multilaterally developed society in Romania."

A Profound Humanism of Our Socialist Order

In our party's view, the possibility of providing as diversified consumption as possible for all the working people, of continually raising the standard of living and the quality of life, is based on the constant development of the production forces, their sensible distribution over the territory, the priority growth of the efficiency with which the resources of society are expended. Only in this way is it possible to ensure the growth of national income, of the newly created value as a unique source for raising the population's incomes, its standard of living. At the same time,

the establishment of a fair division between the accumulation fund and the consumption fund, depending on the conditions specific to each stage of development of the economy, and the setting of the part of national income earmarked for development at about one-third have permitted the creation of the material support for dealing with the consumption demand of the population. Favorable premises for reducing the objective gap between the consumption demand and the economy's capacity to meet it have been created by founding every year new units in the branches and subbranches that respond directly to public consumption, by increasing, diversifying and qualitatively improving their production.

However, it is unquestionable that the sphere of the concept of well-being, of standard of living and quality of life, is more comprehensive. The quality of life under socialism expresses the totality of the conditions that provide for the harmonious development of the human being--on a biological, social and spiritual plane--the satisfaction of his aspirations at a higher and higher level. On another plane, the obtaining of a higher quality of life presupposes the harmonization of individual interests with society's general aspirations, the multilateral fulfillment of the human personality, the utilization of all the capacities and talents of each for the common good.

Exhibiting a more concrete, more "quantifiable" character, the concept of standard of living refers to the degree to which the material and spiritual needs of a society, social class or person are satisfied, under the given conditions of development of the production forces, of social production. A number of quantitative and qualitative determinations expressed by means of economic and social indicators are utilized to characterize the standard of living. These indicators pursue the measurement of the level of the population's nominal and real incomes, of the level of the consumption of material goods and services per capita, of the population's state of health and of accessibility to services of health care, of education, culture and art, to working, housing and recreational conditions, and to the general state of the natural environment in which the people live and work. At the same time, these economic and social indicators permit the distinguishing of the ways, the directions of action by means of which a continual rise in well-being will be provided.

The Progress of the Economy's Development--the Basis for Raising the Quality of Life

The development of the national economy at a high rate in the period of socialist construction has provided the material base needed to continually raise the well-being of all the working people. Occupying the leading places in the world with regard to the progress of economic development, Romania achieved a 13-fold increase in national income, with an average annual rate of 9.7 percent, in the 1950-1978 period. The increase in national income and the achievement of a sensible allocation of it to the development fund and the consumption fund have permitted, along with the rise in

the rate of the development fund, a continual increase in the consumption fund. At the same time, the consistent application of the policy of socialist industrialization and of harmonious development of all branches of the national economy has had major effects on the employed population. Thus, the percentage of the population employed in the nonagricultural branches has risen from 29.5 percent in 1950 to 70.9 percent in 1980, including 44.4 percent in industry and construction, as compared with 12 percent in 1950. The attraction of a larger and larger volume of manpower to the nonagricultural branches and the systematic growth of the population's incomes from wages have led to the growth of the wage fund by a factor of 21 in 1980 as compared with 1950. The average net wage has risen to 2,261 lei (at the end of this year), as compared with 1,595 lei in 1975 and 337 lei in 1950.

In their turn, the peasantry's incomes obtained from work in the CAP /agricultural production cooperative/ and on the personal farm, calculated per employed person, have risen 8.3-fold, with a significant role going to the providing of an increase in the guaranteed minimum income to 1,500 lei per month for those who work in zootechny and irrigation and to 1,200 lei for those who work in vegetable-, vine- and fruitgrowing. In addition, the incomes obtained by the population from the social consumption funds have risen, especially through the increase in pensions, in the state allocation for children, in the funds earmarked for the development of education, health care, social and cultural actions.

The increase in incomes, concomitant with the growth of production, the continual diversification and improvement of the quality of consumer goods, has caused a substantial rise in the population's consumption for all categories of products. The growth of the average annual consumption per capita for a number of basic food products is indicative in this regard: from 16.7 kg in 1950 to 62.4 kg in 1980 for meat and meat products; from 107.6 liters to 220 liters for milk and milk products; from 79 units to 270 units for eggs; and from 6.9 kg to 30 kg for sugar and sugar products. The level of the consumption achieved for the main food products provides to the whole population a balanced state of nutrition, in relation to the physical effort exerted and to age. For nonfood goods the average annual consumptions per capita are also continually rising. The development and modernization of light industry and the diversification of the production in this branch are providing for the population's consumption needs for the main products. The average annual consumption per capita has risen from 13.19 square meters in 1950 to 29.10 square meters in 1980 for cloth (including garments) and from 0.62 pairs to 4.10 pairs for footwear--to refer to just a few usual indicators.

Along with the growth of the population's incomes and the fuller and fuller satisfaction of the need for food and clothing, the degree to which the population is supplied with durable goods has also risen--this constituting in fact a significant change in the structure of the population's consumption, one that indicates the approach of the type of consumption in our

country to that existing in the industrialized states. In addition, the degree to which the population is supplied with devices for home use (refrigerators and washing machines), with radios, television sets and other goods, has risen. Remarkable results have been obtained with regard to the housing conditions of the population. In the current five-year period alone, about 1 million apartments will be achieved from state funds. Over 15 million citizens in cities and villages now live in houses built in the past 30 years.

1981-1985: a New and Significant Stage in the Process of Growth in Well-Being

The basic coordinates of the growth of the material and spiritual well-being of our people in the 1981-1985 five-year period have found themselves a coherent and harmonious expression in the Directive Program for Increasing the Standard of Living in the 1981-1985 Period and Continually Raising the Quality of Life, a document adopted at the 12th Congress of the Romanian Communist Party. Being based on the objectives established by the congress with regard to the transition of Romania to a new phase of development, in which the strong affirmation of the scientific and technical revolution will occur, and the speedup of the process of turning the economic and social activity to a new quality, this program incorporates in an organic whole the main orientations and means that will permit the raising of the well-being and the level of civilization of our whole populace to a new stage in the next 5 years.

Starting from the direct correlation that is established between the growth and development of the national economy in general, between the growth of national wealth and the possibilities of raising the material and spiritual well-being of the population, the necessity of acting to achieve a new, higher quality in all economic activity is stressed in the party documents. The management of material and financial resources with maximum efficiency and the achievement of a substantial rise in labor productivity in all economic units--these are the real ways by means of which it is possible to provide the necessary conditions for satisfying the population's demands and raising its standard of living. "It is necessary," Comrade Nicolae Ceausescu stated in the report presented at the 12th party congress, "for all working people and all party organizations to do everything so that our entire economic activity is performed with the highest efficiency, providing for the continual growth of national wealth, the sure basis--and the only basis--for continually developing the homeland, for raising the well-being of the people."

As thus far, the development of the national economy at a steady rate, the more marked growth of national income and its sensible allocation--70 percent to the consumption fund and 30 percent to the accumulation fund--will constitute the basic premises for enlarging the wage fund and increasing the amount of expenditures for social and cultural actions and the investments for the facilities from which the population benefits directly. The

growth of national income at an average annual rate of 6.7-7.4 percent will permit the growth of the wage fund by 43.3 percent in 1985 as compared with 1980 and of the expenditures for social and cultural actions by 25 percent, including those from the state budget by 24 percent. In the next five-year period, another 930,000 new workplaces will be created--an action with a direct effect on the growth of the number of worker personnel, especially in industry and construction, and on the growth of the incomes of the working people by this means too. Significant changes will occur in the structure of the employed population, a process with similar effects.

The provisions on growth in the population's direct incomes from work in accordance with remuneration according to the quantity, quality and social importance of the work occupy an important place among the ways to systematically improve the material, social and cultural living and working conditions of the population (also see Table 1).

Table 1. The Main Indicators of the Population's Incomes in 1980-1985*

	1980 (lei per month)	1985 (lei per month)	(provisions) Growth in 1985 as compared with 1980 (%)
Average real wage	2,261	2,670	16-18
The peasantry's real incomes resulting from work performed in agriculture, per employed person, including:	1,380	1,725	25
Incomes of cooperative members	1,388	1,741	25.4
Incomes of peasants with an individual farm	1,340	1,650	23.1

* Drawn up on the basis of "Programul-Directiva de Crestere a Nivelului de Trai in Perioada 1981-1985 si de Ridicare Continua a Calitatii Vietii" /The Directive Program for Increasing the Standard of Living in the 1981-1985 Period and Continually Raising the Quality of Life/, Politica Publishing House, Bucharest, 1979.

The increases in pay will be achieved in such a way as to maintain a fair ratio between the minimum wage and the maximum wage in the economy, which is 1 to 5.5 for the current stage. On this basis, the net minimum wage will amount to 1,630 lei, as compared with 1,425 lei in 1980. In addition, in the next period of the five-year plan, on the basis of fulfilling the targets for growth in economic efficiency and labor productivity, the sums allocated to the profit-sharing fund will be gradually raised, providing an increase in the average sum per person by about 50 percent in comparison with 1980. The peasantry's incomes resulting from agriculture will be raised 20-25 percent.

The increasing of the funds earmarked for social and cultural actions constitutes an important way to raise the standard of living and improve the

quality of life. In this regard, it is expected that the total social and cultural expenditures will rise 37 percent in the 1981-1985 period, amounting to 14,200 lei per family in 1985, with the social and cultural expenditures financed from the budget coming to 12,950 lei per family, as compared with 10,000 lei in 1980. As a result of the growth of the state social security pensions, the military pensions, the pensions for IOVR /invalids, orphans and war widows/ and other categories of pensions on the average by about 23 percent for the nominal ones and 15-16 percent for the average real pension, the expenditures for them from the state budget will rise 38 percent on the average for the five-year period in comparison with the 1976-1980 five-year period.

The rise in the monetary incomes of the population under the conditions of a rigorously controlled evolution of the price and rate index will be correlated with an increase in the volume of the retail sales of goods by 36.5 percent in comparison with 1980. As follows from Table 2, the biggest increases will be registered for the consumption of nonfood products and especially of durable products.

Table 2. The Level of the Consumption of the Main Food and Nonfood Products in the 1980-1985 Period*

	Unit of measure	1980	1985	Growth in 1985 as compared with 1980 (%)
Food products per capita				
Meat and meat products	kg	62.4	68-72	9.0-15.4
Milk and milk products (excluding butter)	liters	220	230-240	4.5-9.1
Sugar and sugar products	kg	30	33-35	10.0-16.7
Eggs	units	270	275-280	1.8-103.7
Vegetables and vegetable products	kg	143.6	150-160	4.5-11.4
Fruit and fruit products	kg	63.0	75-85	19.0-34.0
Nonfood products per capita				
Cloth (including garments)	square meters	29.1	35.9	23.4
Knitwear	units	9.9	14.2	43.4
Footwear	pairs	4.1	4.1	-
Durable good per 1,000 inhabitants				
Radios	units	247	300	21.5
Television sets	units	203	245	20.7
Refrigerators	units	157	220	40.1
Washing machines	units	100	153	53.0
Automobiles	units	28	57	103.6

* Drawn up on the basis of "Programul-Directive de Crestere a Nivelului de Trai in Perioada 1981-1985 si de Ridicare Continua a Calitatii Vietii."

Along with the increase in the degree to which the food and nonfood needs are satisfied and the rise in the degree to which the population is

supplied with durable goods, a rapid increase and a wide diversification of the population's demand for services will occur. Accordingly, a rise in the volume of services by 54 percent, representing 74.6 billion lei in 1985, is expected. In addition, in the next 5 years the efforts to provide better and better housing conditions will be increased. Thus, about 1.10 million apartments will be built from the investment funds of the state, including 440,000 apartments earmarked for sale to the population. About 100,000 dwellings will be built from the population's own funds. For improving the comfort, the number of apartments with 3-4 rooms will increase, there being provided an average number of rooms per apartment of 2.52 and an increase in the average floorspace per capita in cities to 10.6 square meters, as compared with 9.7 square meters in 1980.

Inseparable components of the quality of life, education, culture and art, health care, sports and tourism, and their development will be supported by significant budgetary allocations. Thus, the expenditures for education will increase over 36 percent. The conditions for preparing for the generalization of secondary education, for expanding higher education and for more closely connecting all education with the practical needs of socialist construction in our country will be created. The expenditures for health care will be increased about 32 percent, and those for culture and art will be increased 26 percent. In addition, as a result of the growth in the degree of technical equipping of the economy, the improvement in the organization of production and labor, and the increase in labor productivity, the 2d stage of the program of measures for reducing the duration of work to 44 hours will be undertaken in the next five-year period.

All these orientations and measures established by the 12th congress reflect the constant care and concern of our party and state for achieving a higher and higher level of well-being for our whole population.

Domestic Trade Role Examined

Bucharest REVISTA ECONOMICA in Romanian No 34, 22 Aug 80 pp 11-12

/Article by Dr Virgil Adascalitei and Dr Aurel Valner of the Institute of Economics of Domestic Trade and Tourism: "Socialist Trade's Contribution to Implementing the Policy of Raising the Standard of Living of the Whole Population"/

/Text/ In the 36 years that have passed since the revolution of liberation, Romania has experienced immense revolutionary changes, splendid achievements in all fields of activity. The successful performance of the historic work of socialist construction and the transition to the forging of the multilaterally developed socialist society have been marked, for the whole populace, by the results of attaining the basic goal of our party's policy--continual growth in material and spiritual well-being, a process that, especially after the Ninth RCP Congress, has accelerated and has considerably expanded its sphere of inclusion, involving on a general plane

the creation of a new quality of life. Socialist trade, which, as an important component of our national economy, has continually increased its contribution to raising the standard of living of the population in the cities and villages, has joined in this dynamic process with a significant role.

The country's economic potential in a continual quantitative and qualitative upswing, the growth in national income, the improvement in the socialist relations of production and distribution, and the greater and greater, continually renovated and diversified production of consumer goods are causing the year-to-year growth both of the population's purchasing power and of the possibilities of covering it with a suitable supply of goods. Limiting ourselves just to the analysis of one of the indicators that characterize the vitality of the purchasing power—namely, the evolution of the average net wage of the worker personnel—we find that an increase of it to more than double, that is, from 1,028 lei per month in 1965 to 2,108 lei in 1979, occurred in the past 15 years.

Having the mission of putting at the population's disposal a supply of goods undergoing continual growth, renovation and diversification, capable of satisfying the many and varied consumption demands, Romanian trade has experienced, especially in the period of a decade and a half that has passed since the ninth party congress, systematic, complex and innovative development. Illustrative in this regard is the "retail sales of goods" indicator, which totals over 1.92 trillion lei for the whole 1966-1980 period, under the conditions in which the achievements in 1980 will be about 3.5 times greater than those in 1965. The fact that the average volume of sales per quarter in 1980 is equivalent to that achieved in all of 1964 is extremely revealing.

Moreover, we can deduce how much the dimensions of commercial activity have grown from the fact that in 1980, on the average per workday, goods with a total value of over 700 million lei, as compared with 306 million lei in 1970 and 208 million lei in 1965, and 17.5 times higher than in 1950 are sold.

As an embodiment of the strategic choices of great importance to the present and future of our homeland, established by the Romanian Communist Party and its secretary general, Comrade Nicolae Ceausescu, the rate of growth of the sales of goods in the past 15 years is characterized by high levels with a trend of growth (Table 1).

Another extremely significant aspect also follows from the data presented: the continual and substantial increase, from one period to another, in the absolute value of 1 percent of growth in the retail sales of goods.

Trade has made a notable contribution to our party's continual effort to provide to the people material conditions of life and comfort closer and closer to those in the economically advanced countries, there being

suggestive in this regard the fact that, under the conditions of the growth of the country's population from 19 million inhabitants in 1965 to over 22 million at present, the average sales per capita have risen from 3,350 lei to about 9,600 lei.

Table 1. The Evolution of the Retail Sales of Goods

Period	Volume of sales of goods (billions of lei)	Average annual rate of growth (%)	Absolute value of 1 percent of growth (millions of lei)
1966-1970	406	8.0	638
1971-1975	599	8.5	940
1976-1980	about 917*	8.7	1,407

* The data for 1980 represent estimates.

The steady orientation of the party's policy in the direction of achieving a harmonious territorial structure for the Romanian economy, based on scientific objectives and criteria, has also been reflected in the development of socialist trade. The trend of marked homogenization, on a territorial basis, of the supplying of goods to the population is characteristic, especially of the past three five-year periods. In this regard, the evolution of the retail sales of goods shows that rates appreciably higher than the national average have been registered in counties like Bistrita-Nasaud, Botosani, Covasna, Gorj, Ialomita, Olt, Salaj, Teleorman, Vaslui and others, once lagging behind from this viewpoint too.

Continual qualitative changes have also occurred in the structure of commercial activity. The changes in the content of the supply of goods put at the population's disposal are situated in the forefront. Along this line of thinking, two extremely significant traits are noted:

A better and better positioning of food products with a high nutritive content among the sales;

The growth, at extremely fast rates, of the sales of industrial products that contribute directly to raising the degree of civilization and comfort.

In synthetic terms, these changes are reflected in the elements of the graph below, from which it follows that, according to the laws of consumption, a percentage of 51 percent of the total sales goes to nonfood goods in 1980, as compared with 49.8 percent in 1965.

Referring to food products, more marked increases in sales have occurred for dressed meat (3.1 times more in 1980 than in 1965), meat preparations (4.7 times) and fresh fruit (7.2 times). As a consequence, significant changes regarding the ratio between the sales achieved for various food products, in favor of those important for rational nutrition, have occurred during this period of time:

To 100 tons of bread sales there correspond (tons):	1965	1980*
Dressed meat	8.9	19.1
Meat preparations	3.1	10.0
Cheese	2.2	4.6
Sugar	10.8	15.9
Sugar products	3.4	6.2
Fresh vegetables	18.2	59.0
Fresh fruit	2.8	13.8
Canned vegetables	2.5	6.6

* Estimates.

Graph: The Evolution of the Structure of the Retail Sales of Goods According to Sectors in Socialist Trade

Key: 1. Nonfood goods 2. Food goods 3. Public food

One characterisitc of the rise in the standard of living of the population in our country is, beyond doubt, also that the wardrobe of all categories of citizens is more comprehensive at present than in the past and, at the same time, the range of the articles of clothing and footwear is more diversified and more rapidly adapted to the demands for rational renewal. In illustration, we state in this regard that the sales of garments and knitwear will total nearly 22 billion lei in 1980, 3.4 times more than in 1965. Regarding footwear, the 76 million pairs provided for sale this year will exceed by a factor of 2.1 the level in 1965.

The data on what we could call the impressive dynamics of the market for durable goods for home, social and cultural use, for recreation and tourism, are illustrative for characterizing trade's contribution to raising the population's degree of comfort and civilization. Over 6.2 million radios, 5.3 million television sets, 3.8 million refrigerators, 2.5 million

clothes washers, 572,000 automobiles, and furniture with a value of about 64 billion lei have been sold in the 1966-1980 period. It is estimated that at the end of the current year the average number per 1,000 inhabitants will be 247 radios, 203 television sets, 157 refrigerators, 100 clothes washers and 28 automobiles.

A multicriterional judgment of the development of trade also entails the stressing of the continual expansion of the commercial assortment, now composed of a total of about 320,000 positions, of which 200,000 belong to the sector of textile goods and footwear, 90,000 to the sector of metal and chemical goods and 30,000 to the food sector. It is a question, in fact, of an assortment amplification--in horizonal and vertical terms--of great proportions, which closely reflects the continual growth, diversification and renovation of the Romanian production of consumer goods, on the basis of the special programs adopted by the party, on the initiative and with the direct participation of its secretary general, Comrade Nicolae Ceausescu.

However, the results presented regarding trade's contribution to better and better satisfying the consumption demands of the population cannot be judged fully if what has been achieved in the field of the material base of the sector is not taken into consideration. In proportion to the rise in the degree of complexity of commercial activity, in close connection with the structural changes at the level of the consumer, the expansion of the technical and organizational capacity of the trade apparatus has constituted one of the most important lines of action. As a consequence, socialist trade now has over 78,000 retail-trade and public-food units, with an area of nearly 8 million square meters--over 2 times more than in 1965 (see Table 2).

Table 2. The Evolution of the Retail Trade and Public Food Network

Period	The net increase in:		Average annual rate of growth (%)	
	The number of units	The commercial space (thousands of square meters)	Number of units	Commercial space
1966-1970	8,185	1,260	2.9	6.4
1971-1975	10,058	1,625	3.1	6.1
1976-1980*	7,200	1,850	2.0	5.2

* The data for 1980 represent estimates.

This quantitative growth of the network has occurred concomitantly with the concern for increasing the functionality and the degree of modernization of the units of all categories, thus creating ever better conditions for practicing modern, civilized trade. The qualitative changes occurring from this viewpoint are expressed synthetically in, among other things, the continual and appreciable growth of the average area of a unit and the significant improvement in the trade-network/population ratio, as follows:

	1965	1970	1975	1980*
Average area per unit (square meters)	65	77	89	104
Number of units per 1,000 inhabitants	2.8	3.0	3.3	3.5
Commercial space per 1,000 inhabitants (square meters)	182	232	298	366

* Estimates.

Such features as the following are characteristic of what can be called the quality of the trade network:

The reconstruction of trade on modern bases in the central zones, in the capital and in many other cities of the country (Focsani, Galati, Iasi, Piatra Neamt, Ploiesti, Pitesti, Tulcea, Suceava, Vaslui and so on);

The putting of many new stores into operation on the ground floor of the apartment blocks in the recently built districts;

The delineation of an individual character of the network of Romanian trade, characterized by functionality, modernity and diversity;

The concern for as good a placement as possible of the network throughout the country, concomitant with such a structuring in which the most suitable types of units turn up. Indicative in this regard is the fact that 60 large department, general and "BIG"-type /expansion unknown/ stores, with a total commercial space of 350,000 square meters, which achieve a total volume of sales of nearly 15 billion lei per year (11 percent of the total sales in the system of the MCI /Ministry of Domestic Trade/), are operating in 1980;

The founding of a comprehensive network of specialized stores, according to the principle of "the complexes of needs," which operate in many of the cities of the country;

Constant concerns for restructuring the public food network and orienting it toward an accentuated culinary profile;

The construction of new agricultural and food markets and the modernization of the existing ones.

In order to raise the social efficiency of trade, for a greater contribution to the sensible utilization of the time of the consumers, steady action has been taken to promote the modern forms of service. Indicative in this regard are the data from the end of 1979, which show that in the total commercial space of the network of food stores in the system of the MCI those in which self-service is practiced have a percentage of over 7.7 percent. In the sector of nonfood goods too, the modern forms of service have been expanded considerably, especially by means of open display and free choice of the goods, so that over half of the number of units in the system of the MCI operate on the basis of this form of service.

The notable accomplishments obtained by socialist trade are, beyond doubt, the result of the constant activity performed by the worker personnel in this branch, who now exceed 450,000 workers, as compared with 142,000 in 1950 and 293,000 in 1965. Of course, it is also a question of an increase in quality, obtained by means of continual concern for raising the level of professional instruction and conduct.

Like the other branches of our national economy, trade's vigorous development has been based to an ever growing extent on the contribution of scientific research and technical progress. The Institute of Economics of Domestic Trade and Tourism is tackling complex research problems, making many studies for forecasting of the retail sales of goods, at the level of the whole country and on a territorial basis, and studies for complex prospecting of the market for groups of products and main products, which are helping to more sensibly substantiate, on scientific bases, the plan for sales of goods and the territorial distribution of the supply of goods and to better correlate the supply with the demand. In addition, by means of selective field research, by means of panels of consumers and of stores and by means of opinion polls carried out year by year at the Fair for Samples of Consumer Goods, information and analyses of the most useful kind for restructuring the supply of goods in accordance with the demand of the population are put at the disposal of trade and industry.

The path taken by socialist trade and the consistent implementation of the instructions given by the secretary general of the party, Comrade Nicolae Ceausescu, at the National Conference of Working People in Socialist Trade in the summer of 1978 constitute a solid foundation for continual progress in this branch, for a firm engagement in the direction of implementing the historic decisions of the 12th party congress. There is the certainty that socialist trade will register new and numerous achievements in the next five-year period, creating a new, higher quality, under the conditions of an ever greater contribution to increasing the standard of living of the whole populace and continually raising the quality of life.

RELATIONSHIP BETWEEN LABOR FORCE, ECONOMIC DEVELOPMENT VIEWED

Bucharest REVISTA ECONOMICA in Romanian No 33, 15 Aug 80 pp 13-14, 20

[Article by C. Grigorescu: "On the Relationship Between Labor Resourrces and the Modernization of Romania's Economy"]

[Text] Equalization of Labor Productivity Levels

The development of the economy and the modernization of its structure have gone hand in hand with an increased social productivity of labor. During the 1950-1978 period for instance, the employed population grew 1.3-fold while the national income increased 13-fold; this means that during this period, the social productivity of labor, expressed as national income created by one person employed in the economy, has increased 10.6-fold.

This increased social productivity of labor has been supported primarily by a shift of the employed population toward branches with relatively high labor productivity. As has been shown elsewhere, industrial labor productivity during the first years of the building of socialism was about 10 times higher than labor productivity in agriculture. The consequence has been a significant reduction in the population employed in agriculture and forestry -- from 74.3 percent in 1950, to 32.8 percent in 1978 -- and a corresponding increase in the percentage of the population employed in non-agricultural branches, particularly in industry and constructions, during the same years -- from 14.2 percent to 42.5 percent.

The increased social productivity of labor has also been supported by a greater economic efficiency in all branches of the economy. During the 1950-1978 period for instance, labor productivity (calculated as the ratio of net product to employed population) has increased 9.3-fold in industry, 4.0-fold in constructions, and 6.3-fold in transportation and telecommunications. And finally, the increased social productivity of labor has been due to a 5.0-fold increase in agricultural labor productivity, a branch whose labor productivity was the lowest at the onset of the economic reconstruction on socialist bases.

Table 1. Labor productivity levels in branches compared to the average for the economy.

	1950	1965	1970	1978
National economy	100.0	100.0	100.0	100.0
Industry	366.7	254.7	262.2	172.8
Constructions	272.7	126.7	125.6	113.3
Agriculture	37.5	51.3	39.7	47.1
Transportation and telecommunications	195.5	108.1	93.0	115.8

Source: Romania's Statistical Yearbook, 1978, pp 92, 111 (calculated on the basis of the ratio between the branch structure of the national income in current prices, and the branch structure of the employed population).

The changes that have occurred in the branch distribution of the employed population, together with technologic progress throughout the economy and higher qualifications in the labor force, have contributed to reduce the gaps between labor productivity levels, and to introduce a homogeneization of labor productivity in economic branches and sectors (see table 1).

The trend toward homogeneization can be clearly seen in the table. Its important aspect is that it is taking place under conditions of increased labor productivity in all branches of the national economy. One noteworthy feature is the change in agricultural labor productivity as compared to industrial labor productivity. Up to 1970, industrial labor productivity increased much more rapidly than agricultural labor productivity, but after that time the latter overtook the former, and in the 1970-1978 period labor productivity growth was 2.4-fold in agriculture and only 1.6-fold in industry. The fact that agricultural labor productivity increased more rapidly than industrial labor productivity results from the development and modernization of the economy as a whole, the changes that have occurred in the branch distribution of the employed population, and the formation of new professional structures.

Projections of the Employed Population in 1990

Romania is currently undergoing an intense process of economic development and modernization, creating a materially and culturally advanced civilization placed entirely at the service of man. As indicated in the documents of the 12th Party Congress: "The 1981-1990 decade is the decisive stage in fulfilling the fundamental objective of the Party Program for building a multilaterally developed socialist society and for creating the social and material premises for gradual transition to communism." The achievement of this goal imposes a large increase in production forces -- on the basis of a balanced development of industry, agriculture, and the other branches of the national economy -- the adoption of the newest

Table 2. Projected employed population in 1990.

	Number in thousands		Percent structure	
	1980	1990	1980	1990
Employed population	10,400	12,000	100.0	100.0
Industry and constructions	4,663	6,240	44.8	52.0
Agriculture	2,975	1,800	28.6	15.0
Other branches	2,762	3,690	26.6	33.0
Working personnel	7,420	9,500	71.4	79.2

advances in science and technology, a superior utilization of material resources and social labor, and a modernized production structure, so that the 1981-1990 decade will trully become "the decade of science, technology, quality, and efficiency." During the next decade, Romania will become a country with an intermediate level of economic development, and will hasten its equalization with economically advanced nations.

The current stage of socioeconomic development requires that the superior utilization of social labor acquire new quantitative and qualitative values. The objective of achieving, by 1990, the broad outlines for building a multilaterally developed socialist society, and for more fully satisfying the needs of all the nation's inhabitants, imposes a rapid rate of economic growth with higher efficiencies in all sectors of activity. A special position in this framework is filled by continued improvements in the utilization of the work force, linking this process with the modernization of the economic structure and with a better distribution of the work force among branches. According to present estimates, the population employed in the national economy, and its distribution among branches in 1990, will appear as shown in table 2.

The trends in the branch distribution of the employed population obviously correspond to the country's present stage of development. As has already been shown, a country's transition into the stage of developed nation assumes an increase in the size and proportion of the population employed in non-agricultural branches.

By continuing its industrialization policy, by having 52 percent of its employed population in industry and constructions, and by maintaining a sustained growth in the efficiency of social labor, Romania will become a powerfully industrialized nation, a decisive condition for its entry into the ranks of economically advanced nations. But it is also true that at an advanced stage of economic development the industrial population undergoes a certain reduction. In some economically developed countries such as Italy and England, the proportion of the employed population in industry and constructions fluctuates around 40 percent, whereas this percentage is much higher in FRG -- 45.1 percent in 1978.

It is well known that Romania has the soil and climate needed to achieve a strong, efficient, and highly productive agriculture. That is why agriculture is a basic branch of the economy in our country, and why its current and future development is one of the highest priorities of the economic reconstruction. The profound agrarian revolution which will take place during the 1981-1985 five-year plan, and which will cover both the technico-material base and the organization of production, will increase agricultural production and yields and will further reduce the agricultural population. Unlike other countries however, the population employed in our agriculture will be significantly larger, estimated at about 15 percent. But the achievement of the agrarian revolution also requires a revolution in the training of agricultural workers, as well as improvements in the sex and age distribution of these workers.

During the 1981-1990 decade, conditions will be created for a stronger development of activities in the tertiary sector. At the same time, an optimum development of this branch is an essential condition for increased economic efficiency and for satisfying the needs of the population: hence the increased percentage of the population employed in this sector, from 26.6 percent in 1980, to 33 percent in 1990.

In final analysis, the branches and sectors of the national economy develop as a function of the population's needs. As such, the distribution of the labor force among branches depends on these needs and on the social productivity of labor. It is therefore evident that the structure of the labor force will change together with these factors. Yet, the facts show that labor productivity and the population's needs are growing at unequal rates. After 1970 for instance, industrial labor productivity was surpassed by agricultural labor productivity. But compared to the productivity in these branches, labor productivity in many branches of the tertiary sector is undergoing moderate growth. As to the elasticity of the population's demand for goods and services, the data shows that this elasticity is higher for industrial products than for agricultural ones (for some of these goods, the elasticity is even less than one).

It should be mentioned however, that as incomes increase, and as the demand for agricultural and industrial products becomes saturated, there will also arise a large increase in the demand for consumer services and implicitly for employed manpower. Given the high elasticity of the population's demand for some activities in the tertiary sector, it is not impossible that as a whole, the population employed in this sector will exceed 33 percent. Following 1990, however, this proportion will be much higher, and could even reach much higher values than those currently found in economically developed nations. But the structure of the tertiary sector will be quite different from that of capitalistic countries. The preponderant activities will be those which serve the natural needs of the population, especially creative activities. At the same time, we can already suggest that by 1990 there will occur a slight reduction in the population employed in industry, because labor productivity will reach the levels found in advanced nations, and because the elasticity of the population's demand for industrial goods is relatively low when needs are well satisfied.

Sources of Necessary Manpower

Projections of the population employed in the national economy and in branches, as shown in table 2, assume that the 1981-1990 decade will see a rapid rate of economic growth based on a 30 percent capital growth and on greater efficiency in all branches of the economy. As has been true until now, the achievement of this capital growth requires a significant increase in labor resources. The data indicates that the next decade will witness an increase of 1.6 million employees in the economy as a whole (a rate of 1.4 percent), of 2,775,000 persons in the non-agricultural population (a rate of 3.2 percent), and of 2,080,000 industrial workers (a rate of 2.5 percent). The additional demand for labor resources raises the problem of meeting that demand; to what extent therefore, will the sources of manpower (numbers) and implicitly the mobility of the work force among branches and professions according to these projections, assure a rapid rate of economic growth.

To begin with, we note that during the next decade the growth rate of the population employed in the entire economy is much higher than that recorded for the 1951-1978 period, namely 1.4 percent as compared to 0.7 percent. If we consider that during the next decade the natural increase in the working-age population will be only 787,000 people (a rate of 0.6 percent), it will be necessary to bring into the working ranks significant contingents of housewives, or of those who although of working age, are not employed for one reason or another. Another source of employees could be those who are retired but who want to continue their activities. Of the total increase in the population employed in the national economy, 50 percent will therefore have to be derived from the natural increase in the working-age population, and 50 percent from housewives and others categories of the population. To the extent to which these population categories do not provide the expected increase in the population employed throughout the economy, the labor force appears as a restriction on the development and modernization of the economic structure. All of which is further argument for the best utilization of the existing work force and for a considerable increase in labor productivity.

The figures in table 2 show a more rapid increase of the population employed in non-agricultural branches than that of the total employed population, both as absolute numbers and as percentages. And while it is true that the growth rate of the non-agricultural population is somewhat lower than during the 1971-1980 decade (3.2 percent compared to 4 percent), its absolute magnitude is estimated to be sensibly larger (2,775,000 persons against 2,400,000 persons).

The problem of meeting the projected increase in the non-agricultural population is the same as the one that arises for the total employed population. A primary source is found in all the population categories which provide the total growth of the population employed throughout the economy (natural increase in the working-age population, housewives, retirees, and so on). But these sources cover only about 58 percent of the

Table 3. Sex and age characteristics of the agricultural population.

	1956	1977
Agricultural population	100.0	100.0
Women in the agricultural population	53.7	57.8
Up to 29 years-old	38.0	10.9
30-39 years-old	17.0	17.6
40-49 years-old	17.9	24.7
50-54 years-old	7.9	21.9
55-59 years-old	6.9	18.8
60-64 years-old	12.3	6.1

Note: The 1977 data refers to the cooperative sector.

increase in the non-agricultural population. Another source for covering the additional needs for workers in non-agricultural branches will therefore have to be the population employed in agriculture, which in turn will be reduced by the mechanization of agricultural operations; these people will thus be drawn into industry, constructions, and other non-agricultural branches. However, the proportion of this source in the total growth of the non-agricultural population will be smaller than in the past, namely 42 percent as compared to 60 percent during the 1951-1978 period.

Although this proportion is smaller than in the past, the agricultural population will continue to play a significant role in providing the work force necessary for a continued policy of national industrialization and modernization of the economic structure. To be sure, this raises several problems: on one hand, the extension of mechanization in agricultural work must make available the agricultural manpower while improving this agricultural work; and on the other hand, agricultural workers must become qualified to perform industrial, construction, and other non-agricultural trades.

While stressing the need that the agricultural population contribute to an increase of the personnel in non-agricultural branches, we must at the same time note that as compared to the situation of the first years of the building of socialism, the current labor resources in agriculture have some age and sex characteristics that limit their entry into non-agricultural branches (see table 3).

The data in table 3 is eloquent. It indicates a modification in the sex and age structure of the agricultural population, due to the fact that the non-agricultural branches have attracted primarily the young and male work force. However, a continuation of this process would create difficulties for the development and modernization of agriculture, and would further stress the lack of young manpower which is observed in many agricultural production cooperatives.

There is no doubt that more extensive mechanization will release the agricultural manpower which would then become employed in non-agricultural branches, but as we have noted, its age structure limits its attraction into non-agricultural branches. First of all, the schooling of the agricultural population is poorer, which implies the entry of this population into trades that require relatively low qualifications. And we are equally aware of the fact that given the inertia of an older population, it is difficult for it to adopt new work methods, which are specific to industrial activities and which usually are conducted outside of the localities in which this population lives. In the light of the above, the location of industrial objectives, small enterprises, or sub-sections of enterprises in neighboring towns, will ease the attraction of the agricultural population into non-agricultural branches.

We therefore draw the following conclusions:

1. During the 1981-1990 period, the work force and particularly the natural growth of labor resources, will restrict the development and modernization of the economy. To overcome this restriction, we must expand the intensive factors of economic growth, improve the organization of production and labor, and promote technical and scientific progress on a wide scale.

2. Because the modernization of economic structures requires significant changes in the structure of the work force by professions and branches of the economy and industry, and because the natural increase in labor resources (young population trained in professional schools, high schools, and higher education) is relatively low compared to the growth of the non-agricultural population (28.4 percent), it must be assumed that professional mobility among the ranks of the employed population will intensify during the 1981-1990 period. The most efficient achievement of this process requires improvements in the broad specialty education of young workers, as well as broader retraining and better professional training.

3. A policy for encouraging birth rates and for a normal population growth rate, remains the basis for assuring the work force resources necessary for the development of the national economy.

DECREE ON REORGANIZATION OF OLTENIA MINING COMBINE

Bucharest BULETINUL OFICIAL in Romanian Part I No 49, 20 Jun 80 pp 1-2

/Decree of the State Council of the Socialist Republic of Romania on Some Measures for Reorganizing the Oltonia Mining Combine/

/Text/ The State Council of the Socialist Republic of Romania decrees:

Article 1. On the date of 1 June 1980, the Rovinari-Rogojelu Mine, the Rosia Jiu-Pesteana Quarry and the Lupoaia Quarry, economic units without a legal personality, under the subordination of the Oltenia Mining Combine, are reorganized as follows:

a) The Rovinari-Rogojelu Mine, into "the Urdari Mining Enterprise," with headquarters in the Bilteni Commune, Gorj County, having as an object of activity the extraction of lignite, the execution of mine-opening work and geologic, hydrogeologic and drainage work and the execution of repair work on equipment and services;

b) The Rosia Jiu-Pesteana Quarry, into "the Rosia Jiu-Pesteana Mining Enterprise," with headquarters in the Parcasesti Commune, Gorj County, having as an object of activity the extraction of lignite, the execution of geologic, hydrogeologic and drainage work and the execution of quarry-opening work, repair work on quarry equipment and services;

c) The Lupoaia Quarry, into "the Lupoaia Mining Enterprise," with headquarters in the Catunele Commune, Gorj County, having as an object of activity the extraction of lignite, the execution of geologic, hydrogeologic and drainage work and the execution of quarry-opening work, repair work on quarry equipment and services.

Article 2. The enterprises founded in accordance with Article 1 operate under the subordination of the Oltenia Mining Combine, on the basis of the principle of economic and financial self-administration, with a legal personality, and are organized on the basis of the legal provisions on the organization and management of the socialist state units and of the uniform structural standards for the coal industry and the mining extractive

industry, approved by means of Decree No 162/1973 on the Establishment of the Uniform Structural Standards for the Economic Units.

Article 3. On the date of 1 June 1980, the Station for Heavy Equipment for Construction, an economic unit without a legal personality, in the structure of the Oltenia Mining Combine, will operate within the Rovinari Transportation Enterprise, which is reorganized into "the Rovinari Enterprise for Transportation and Heavy Equipment for Construction," with headquarters in the Farcasesti Commune, Gorj County, having as an object of activity the performance of transportation with motor vehicles, the maintenance and repair of construction equipment and of its own fleet of means of transportation, and services.

The Rovinari Enterprise for Transportation and Heavy Equipment for Construction operates under the subordination of the Oltenia Mining Combine, on the basis of the principle of economic and financial self-administration, with a legal personality, and is organized in accordance with the legal provisions on the management of the socialist state units and with the uniform structural standards for the activity of transportation and for the activity of industrial construction, approved by means of Decree No 162/1973.

The Rovinari Enterprise for Transportation and Heavy Equipment for Construction belongs to grade I of organization and to group IV of branches. The enterprise will have distinct indicators established for the basic activity--automotive transportation and services.

The Station for Heavy Equipment for Construction maintains its grade II of organization and its placement in group IV of branches.

Article 4. The Urdari Mining Enterprise belongs to grade I of organization, group II of branches, and applies for mineworkers pay level B of the network of, respectively, underground or surface mines, in accordance with the provisions of Law No 57/1974 on Payment According to the Quantity and Quality of Work.

Article 5. The Rosia Jiu-Pesteana Mining Enterprise belongs to the special grade of organization, group III of branches, and applies for workers who operate high-capacity equipment, as well as for workers who work in the maintenance, inspection and repair of it, pay level B, piecework or overhead, respectively, of the surface mine network, in accordance with the provisions of Law No 57/1974 on Payment According to the Quantity and Quality of Work.

Article 6. The Lupoaia Mining Enterprise belongs to grade I of organization, group III of branches, and applies for workers who operate high-capacity equipment, as well as for workers who work in the maintenance, inspection and repair of it, pay level A, piecework or overhead, respectively, of the machine-building network and for quarry mineworkers pay level B

of the surface mine network, in accordance with the provisions of Law No 57/1974 on Payment According to the Quantity and Quality of Work.

Article 7. The structural standards for the units in the coal industry, approved by means of State Council Decree No 270/1977 on Some Measures for Improving the Organization and Activity in the Coal Industry, are modified in accordance with Appendix 1.*

Article 8. The subunits that are founded or are reorganized within the coal industry belong to the grades of organization stipulated in Appendix 2.*

Article 9. The worker personnel who move to the units that are founded or reorganized in accordance with the provisions of the present decree are considered transferred for the sake of duty.

Article 10. The worker personnel transferred for the sake of duty or moved in the same unit to positions with lower pay levels, as a result of the application of the provisions of the present decree, have the right, for 3 months after the date of transfer or movement to such positions, to the basic wage possessed, in accordance with Article 21 of Decree No 162/1973 on the Establishment of the Uniform Structural Standards for the Economic Units. The difference in pay is borne by the units at which the personnel will be employed.

Article 11. The assets and liabilities established on the basis of the balance sheet concluded on 31 May 1980, together with the economic and financial plan indicators, as well as the economic contracts concluded, pass, on the basis of a protocol, from the Oltenia Mining Combine's own activity to the Urdari Mining Enterprise, the Rosia Jiu-Pesteana Mining Enterprise, the Lupoaia Mining Enterprise and, respectively, the Rovinari Enterprise for Transportation and Heavy Equipment for Construction.

Article 12. The Urdari Mining Enterprise, the Rosia Jiu-Pesteana Mining Enterprise and the Lupoaia Mining Enterprise are supplied with one automobile each for the transportation of persons on official business.

Article 13. Appendices 1 and 2 are an integral part of the present decree.

Article 14. Appendices 1 and 2 to Council of Ministers Decision No 367/1973 on Some Measures for Reorganizing the Industrial Centrals, the Units Equivalent to Them, and State Enterprises are amended in accordance with the present decree.

Article 15. Articles 1, 3 and 7, Paragraph 1, of State Council Decree No 27/1978 on Some Measures for Improving the Organization of the Oltenia

* The appendix is communicated to the institutions involved.

Mining Combine, under the Guidance and Control of the Ministry of Mines, Petroleum and Geology, are repealed.

Nicolae Ceausescu,
Chairman
of the Socialist Republic of Romania

Bucharest, 18 June 1980.

ADEQUATE FODDER BASE ESSENTIAL FOR ANIMAL PRODUCTION

Bucharest REVISTA ECONOMICA in Romanian No 33, 15 Aug 80 pp 10-11

[Article by Nicolae David]

[Text] The biological production capability of animals, even for the most productive breeds, can be exploited only when they are adequately maintained and receive complete and balanced fodder rations. Fertility, fecundity, birth rate, prolificness, death rate, viability, and rate of growth for young animals or for those being fattened, as well as the index of feed conversion, are all directly or indirectly influenced by the quantity and quality of the fodder that is being administered.

Modern feeding techniques seek to establish not only a physiologic balance, but maximum production as well, by supplying fodder rations that vary as a function of age, sex, direction of growth, production, and so on. This is the only way to provide the animals with optimum conditions for utilizing their production capabilities. Rational feeding also guarantees a better capability for defense and resistance against various diseases. If to this, we add the fact that feed expenses are the major portion of animal husbandry costs for all breeds and categories of animals (50 percent for dairy cows and 70-80 percent for meat animals), we complete the range of arguments in favor of devoting particular attention to the feeding of animals.

The secretary general of the party, Nicolae Ceausescu, clearly stressed this need at the Workshop of the Central Committee of the RCP, on 25-26 February of this year: "... the matter of fodder for animals is an exceptionally important task: we will not have the needed animals and animal production unless we assure their fodder base."

Some of the basic requirements for instituting a rational feeding system for animals, are:

a) Assuring the quantity of rations, according to breeds, ages, species, sexes, direction of growth, and productive capability of animals;

b) Assuring the quality of rations, expressed in terms of ratios between various nutrients, energy substances, total digestible protein, minerals, vitamins, amino acids, and so on, and the amounts of these nutritional elements in the total quantities of consumed fodder;

c) Assuring the continuity of feeding with the most suitable fodder throughout the year and all year long;

d) Optimum preparation and administration of feeds (in terms of consistency, humidity, number of feedings, and so on);

e) Minimum costs for fodder rations, consistent with obtaining maximum production.

To organize the most efficient feeding for animals, the decision-making organs of agricultural units are faced with a number of technico-economic alternatives, which can lead to various options depending on specific conditions:

Selection of type of feed, taking into consideration agricultural zones, system of maintenance, technology being used, and direction of growth;

For each category of animals, selection of feed varieties with the highest economic efficiency, taking into consideration anticipated productions;

Feeding animals with purchased combined feeds, or producing mixtures of feeds within enterprises (including the purchase and addition of high potency fodder or protein-mineral-vitamin complexes);

Organizing the fodder base and the structure of fodder crops as a function of feed requirements and the technical demands of fodder crops.

Decision-making groups in agricultural units must quantify the respective advantages and disadvantages of each of these alternatives -- and of others that have not been mentioned here -- and must select those with maximum economic efficiency.

Natural Pastures: First Order Fodder Resource

One of the highly valuable fodder resources in our country is the more than 4 million hectares of natural pastures, representing about 30 percent of the nation's agricultural area. Calculations show that natural pastures can provide 40-50 million tons of fodder (in equivalent green mass). The role and importance of natural pastures consist not only in the fact that they cover a large portion of the country's land resources, but also in the economic advantages they have over other fodder. Their low cost per nutritional element and per kilogram of digestible protein, as well as the fact that the fodder is consumed by animals directly in the field (without requiring additional costs for mowing, gathering, transportation, and feeding in stables or corrals), make the green mass in natural pastures into one of the least expensive fodders.

Despite the apparently evident advantages of maintaining animals in pastures, Romania's natural pastures are not used to their full capacities: they are lightly exploited with rather low investments (about 150^lei per hectare). Their yields are consequently small, with low contents of nutritional elements and digestible protein. In hillside areas for instance, the current yield per hectare is 4500-5600^kg of green mass, as compared to 2200-5500^kg in the flatlands, and 2400^kg in the mountains.

Given the extremely important tasks assigned to animal husbandry (in order to increase the number of animals and production, so that animal production will be preponderant in the total agricultural production), it is absolutely necessary that we adopt an intensive system of cultivating and utilizing pastures, so that by 1985 the average production per hectare will double (reaching 10,000-12,000^kg/ha, as included in fodder balance calculations).

As pointed out by the secretary general of the party, we must decisively undertake the cultivation of all pasture and hayfield areas, at least once every four years: "A cultivation plan for pastures and hayfields must be drawn, just as it is for wheat and corn; and this plan must cover seeds and all that is necessary to assure fodder for animals." These cultivation plans and the necessary technical and organizational measures for natural pastures will of course differ for different agricultural zones, or at least for the major natural geographical areas. For the flatlands, the cultivation will include operations similar to those of field crops (plowing, disking, sowing, harrowing, maintenance, fertilizing, harvesting), while for hillside and mountain areas, the major operations will be specific for these zones: mound scattering, removal of bramble patches, tree shoots, and rocks, destruction of weeds, top seeding with perennial grasses of high nutritional value, and soil fertilization (chemically, and especially with organic fertilizers).

At the same time, the intensive and efficient utilization of natural pastures demands that in addition to technologic steps for higher yields, we also take the organizational measures that will allow the most effective exploitation of pastures according to specific conditions.

For instance, for mountain pastures located at large distances from inhabited areas and with poor channels of communication, we must:

Build animal shelters to prevent diseases and death during pasturing periods, wherever there occur premature or late snows;

In addition to shelters, create fodder reserves in pastures, so as to extend pasturing periods and provide fodder in case of bad weather;

Tap springs to assure water for animals and avoid their movement over large distances;

Provide quality bulls for pasturing heifers or cows, especially in poorly accessible areas and those located at large distances from artificial insemination centers;

Provide mechanical milking systems for cows that have beeen accustomed to this type of milking, during the entire pasturing period;

Create access roads between pastures and shelters;

Organize rational pasturing through rotation of several lots;

Organize the gathering and processing of milk in pastures, depending on specific local conditions.

All of these organizational measures are also valuable for other zones in which animals are being pastured, adapting them as needed to the specific conditions of each zone or animal husbandry unit. And finally, flatlands and hillside units also have to solve the problem of fitting pastures into the framework of green belts adopted by each enterprise.

The agricultural units which have taken appropriate technical and organizational steps have succeeded in obtaining spectacular crop increases in pastures, reaching 20,000-40,000 kg of green mass per hectare. In Arges County for instance, the cultivation and rational exploitation of pastures has become a tradition in many localities (Cateasca, Schitu Golesti, Podul Dimbovitei, Dealul Sasului, and so on), where the density of animals per 100 hectares of natural pasture, and animal production, are much higher than the county or national averages.

Superior Exploitation of Secondary Vegetal Products

As a big producer of grains and leguminous seeds, Romania disposes of large amounts of secondary vegetal products (straw, cobs, stalks, and so on), which currently reach about 15-20 million tons per year, the equivalent of 4-6 million nutritional elements.

These secondary products (used as coarse fodder in animal feeding) are known to contain little protein and to have a low index of consumability and digestibility. But the results of scientific research and the experience gained in leading units demonstrate that the preparation and enrichment of coarse fodder before administration to animals increases its protein content as well as its consumability and digestibility, while the additional expenses incurred are recovered in higher animal production and a higher index of fodder conversion. The methods used for preparation can be mechanical (chopping, wetting, scalding, steaming, salting, mixing with molasses), chemical (treatment with alkalies or acids), and biological (fermentation). A particularly important and efficient method has been the use of fodder urea in combination with coarse fodder; and in spite of the positive results obtained with it wherever it has been used, this method has not yet been adequately expanded.

Also increasingly being felt, is the need to adopt steps designed to help and encourage agricultural workers to completely and most efficiently use secondary vegetal products in feeding animals:

a) Planning and record keeping should include a most accurate evaluation of the amounts of secondary products that can be used as coarse fodder, keeping in mind that in the last decades the quantities of secondary products have been reduced with respect to major products, as a result of efforts made to improve the biologic potential of crops, and of the extension of industrial techniques;

b) Measures must be taken to counter the tendency to reduce the amount of secondary products harvested; this is the result of extensive combine harvesting, and of the practice on the part of operators to adjust their machines for higher speeds and consequent higher labor productivity in the case of high crop densities and heavy harvests; however, this sometimes also results in a 20-30 percent loss of the growth mass, which remains in the field;

c) Machines must be provided for the rapid and inexpensive transportation of secondary products. As quantities of baling wire are being reduced, it appears absolutely necessary that agricultural units be provided with an adequate number of specialized machines for straw gathering and transportation (MAC and PAC).

d) In order to increase the nutritional value of straw and cobs, more farms must be endowed with fodder equipment and kitchens for preparing coarse fodder;

e) Greater concern is required on the part of animal husbandry management organs to disseminate the results obtained by experimental stations and leading units, in preparing and enriching coarse fodder, using special courses, exchanges of experience, visual aids, and so on;

f) In order to vest economic interests in the more extensive use of coarse fodder, production cost plans must include the proportion in which this category of fodder is being used and its real cost (although its price per kilogram is low, the cost of a nutritional unit, and especially of a kilogram of digestible product, is much higher than for other fodder categories, as a result of the expenses incurred from harvest time to the time it is administered to animals).

Animal Feeding Solely According to Scientific Standards

Consumption quotas in animal production can be calculated either per unit product (milk, meat, eggs, and so on) or per average animal in a given category (when several products are obtained). The most important of the many consumption quotas is the rigorous foundation of production plans, as well as of income and expenses budgets. The necessary resources of various categories of fodder are calculated on the basis of consumption quotas and plan tasks regarding numbers of animals and animal production. Limiting the amount of fodder that can be consumed to obtain a unit product, to the strictly necessary amount, is an instrument for reducing specific consumption, with outstanding effects on fodder savings, on its superior exploitation, and on more profitable production.

Another function of consumption quotas is the foundation of technical and material supply plans wherever --^in addition to production tasks^-- production stocks and the amount of fodder obtained from internal production are basic indicators which to a large extent determine the fulfillment of the plan.

Both for planning and for analysis, it is extremely important to take into consideration the content and structure of consumption quotas at various stages of supply and production activities. If a technical consumption quota established first by research institutes in a laboratory phase, and then by an experimental phase, represents the amount of material (fodder) effectively used in the production process and therefore at a work site, then a supply consumption quota additionally includes non-technological losses that occur during supply, transportation, preparation, storage, and delivery of the material (fodder) to be used in the production process.

Whereas technical losses, that is the fodder lost during feeding or that which remains unused in stalls, are small compared to the total amount of effectively consumed fodder, non-technical losses represent large amounts which must be included in calculations for determining fodder needs and balances, and the fodder base. Non-technical losses differ greatly for various fodder groups (from 1-5^percent for concentrates up to 10-20^percent for fibrous or succulent fodder, and much higher in some other cases), depending on the technology used in gathering, transportation, and storage, and on the sense of management existing in each agricultural unit that produces, handles, or uses fodder.

Technical consumption quotas refer to the quantity of fodder that must be consumed by an animal in a given period in accordance with planned production, also taking into consideration the technology being used, as well as the level of organization of production and labor.

Although the consumption of fodder in Romania is determined by a regulatory act (Law No^22 of 17^December 1971), the practical application of scientific requirements for feeding animals in all agricultural units has not been fully completed.

The task of agricultural units is to start with established maximum acceptable fodder consumption quotas, as provided by law or by central organs, and taking into consideration the varieties of fodder that can be assured as well as other specific conditions, to establish their own consumption quotas so as to guarantee not only the fulfillment of planned production, but its increased efficiency as well. So that agricultural units which raise animals can formulate more rigorous fodder consumption quotas for themselves, it is imperative that they be provided --^for each category of animal^-- with as many orientation models as possible (from researchers and specialized organs), models which will take into account the productive capability of animals, their physiology, production technologies, type of fodder base, feeding systems, agricultural zones, and so on. At the recent conference with animal husbandry staffs, Nicolae Ceausescu justifiably

criticized the fact that these farms still have few specifications for animal feeding, and he asked that the Ministry of Agriculture, in collaboration with ICNA [expansion unknown], animal specialists, and veterinary doctors, establish specifications for fodder preparation, starting with the best results obtained in our units, and disseminate these recipes to all animal husbandry farms for the rational organization of fodder utilization.

Another requirement is that new tables of nutritional values of fodder (the current ones being mostly outdated) be established based on laboratory analyses conducted during the last ten years, and taking into consideration the changes that have occurred in the structure of the fodder base.

A major need is an improved organization of the feed testing network (particularly of combined feeds), and the establishment for each county, of the nutritional value of fodder as a function of the large variety of conditions in each enterprise.

Only in this way will animal husbandry units be able to benefit from perfected methods in order to establish fodder needs in strict relation to production tasks and specific local conditions, so as to guarantee highly favorable effects on production organization, and on technical and financial results, thus assuring the transition to a new and superior quality in this basic sector of Romanian agriculture.

DECREE ON CONTRACTING PRICES FOR ANIMALS AMENDED

Bucharest BULETINUL OFICIAL in Romanian Part I No 49, 20 June 80 pp 3-4

/Decree of the State Council of the Socialist Republic of Romania for Amending Appendix 2 to Decree No 410/1973 on the Improvement of the System of Contracting and Purchases for Animals, Poultry, Fish and Eggs and the Modification of the Retail Prices for Meat, Meat Products, Poultry, Fish and Eggs/

/Text/ The State Council of the Socialist Republic of Romania decrees:

Article 1. Appendix 2 to Decree No 410/1973 on the Improvement of the System of Contracting and Purchases for Animals, Poultry, Fish and Eggs and the Modification of the Retail Prices for Meat, Meat Products, Poultry, Fish and Eggs, as it was amended by means of Decree No 170/1975, is amended in accordance with the appendix to the present decree.

Article 2. The State Planning Committee and the Ministry of Finance, together with the Ministry of Agriculture and the Food Industry, will make proposals for modifying the economic and financial plan indicators and the state budget for 1980, as a result of the influences that result from the application of the present decree to the plan titulars within the Ministry of Agriculture and the Food Industry, with the indicators for the ministry as a whole remaining unchanged.

Nicolae Ceausescu,
Chairman
of the Socialist Republic of Romania

Bucharest, 18 June 1980.
No 189.

Appendix

Containing the Contracting, Production and Purchase Prices for Live Hogs

Weight groups	Contracting and production prices (lei per kg liveweight)	Maximum purchase prices (lei per kg liveweight)
A. The agricultural production cooperatives, the intercooperative economic associations, and the population's farms		
From 80 to 90 kg liveweight inclusive	8.50	8.50
Over 90 to 100 kg liveweight inclusive	10.50	10.50
Over 100 to 110 kg liveweight inclusive	12.00	12.00
Over 110 kg liveweight*	12.50	12.50
B. The state agricultural units		
From 80 to 90 kg liveweight inclusive	8.30	-
Over 90 to 100 kg liveweight inclusive	9.50	-
Over 100 to 110 kg liveweight inclusive	10.50	-
Over 110 kg liveweight*	11.00	-

* With the exception of culled sows and boars, which will be paid for in the category of "fat hogs of 100-110 kg liveweight."

OPERATION OF ECONOMY IN FIRST HALF OF 1980 ANALYZED

Belgrade PRIVREDNI PREGLED in Serbo-Croatian 3 Sep 80 p 10

[Article by Cedomir Dodig: "Adjustment as Stabilization Progresses"]

[Text] Economic developments in the first half of this year have taken place, as is well known, in the context of the conduct of stabilization policy, that is, the goals and tasks contained in the resolution on the country's economic and social development during the current year.

Especially important to achievement of the measures of stabilization policy are relieving the burden on the economy, bringing all forms of final consumption within the bounds of real capabilities while at the same time ensuring that public and social service expenditure increase more slowly than the social product and income, a more moderate rise of prices, equilibrium in the country's balance of payments, and linkage of personal incomes to the rise of labor productivity in the socialized sector of the economy.

The figures in the table below illustrate the main tendencies of economic developments:

	Index Jan-Jun 1980 / Jan-Jun 1979
Physical volume of industrial output	105
Gross income	134
Costs	135
Income	131
Income distributed	131
Portion of income to finance social services	124
Portion of income to meet general public needs	120
Producer's prices in industry*	122
Prices of farm products	125
Retail prices	127
Cost of living	127

Table (continued)

	Index Jan-Jun 1980 / Jan-Jun 1979
Value of exports	132
Value of imports	108
Investments in fixed capital--total**	125
Economic	120
Noneconomic	138
Current losses	127

* January-July. Unweighted average of monthly index numbers for retail prices and the cost of living.
** January-May 1980.

Favorable Results

One can conclude from the data given and an analysis of their dynamic behavior that the growth of the physical volume of industrial output has been more moderate than in the previous period, which indeed was a goal of the stabilization policy in order to restrict demand on the domestic market and re-establish equilibrium in commodity-money relations.

The pressure on prices rose even more, since in the period January-July 1980 producer's prices of industrial products rose 22 percent over the same period of the previous year, while retail prices and the cost of living rose 27 percent and farm products 25 percent (January-June).

The growth of the physical volume of output and particularly the rather intensive price rise were involved in the relatively high rise of gross income and income of the socialized sector of the economy.

Deterioration of the economic efficiency of the conduct of economic activity is indicated by the fact that costs (index number 135) increased faster than gross income (index number 134). The devaluation measures carried out in the first half of this year had favorable results in that they boosted our economy's exports to the foreign market, but at the same time they tended to increase the operating costs of organizations of associated labor oriented toward imports, which to a considerable extent determined the dynamic relations between costs and gross income.

The measures of stabilization policy and especially the devaluation of the dinar have tended to re-establish more harmonious relations between domestic prices and import prices, which also tended to create more favorable relations in foreign trade, since the value of exports is rising considerably faster (index number 131.8) than that of imports (index number 108.3). However, problems in the field of foreign trade are still very urgent because of the size of the country's payments deficit.

Investment expenditures are restricted to a certain extent, but it should be noted that the growth of investments in fixed capital is still quite high, especially in the noneconomic sector.

Favorable Proportions in Distribution

Secondary distribution: One of the essential prerequisites for fulfilling the Social Plan and also the resolution on economic and social development for this year is to bring public, social service and personal expenditures within the limits of the income the economy earns. That is, redistribution of income outside those limits is a significant source of economic instability and one of the key problems in future development and in strengthening self-management relations in associated labor.

The figures in the table below illustrate relationships in the distribution of income:

	Amounts, in billions of dinars			Composition, %	
	Jan-Jun 1979	Jan-Jun 1980	Index	Jan-Jun 1979	Jan-Jun 1980
Distributed income	392.1	514.5	131	100.0	100.0
A) For social service expenditure	72.0	89.4	124	18.4	17.4
B) For general public expenditure	14.8	17.7	120	3.8	3.5
C) For other purposes	78.5	102.9	131	20.0	20.0
D) For OOUR [basic organizations of associated labor]	226.8	304.5	134	57.8	59.1

The socialized sector of the economy distributed 514.5 billion dinars of income in the first half of this year, which is 31 percent more than in the same period of last year. Proportions in the distribution of income are much more favorable than in previous periods, which means that the measures of relieving the economy of obligations to meet social service and general public purposes are being achieved in part. For example, while the distributed income of the economy was rising at a rate of 31 percent, the share of income for social service expenditures increased 24 percent and the share for general public purposes 20 percent. However, the economy's appropriations to meet social service and public needs are still considerably greater than the proportions set forth in the resolution. Reduction of the share of this portion of income in distributed income helped to increase the share of income for OOUR's from 57.8 percent in the first half of 1979 to 59.1 percent in this period, which has helped to re-establish considerably more favorable relations in secondary distribution of income and to a material strengthening of the position of associated labor.

In Conformity With Economic Policy

Internal distribution: One of the important goals of the resolution for this year and of the measures of stabilization policy as a whole has been to reestablish more harmonious relations in the distribution of net income, that is, in internal distribution. The figures in the table below show relationships in the distribution of net income.

	Amounts, in billions of dinars			Composition, %	
	Jan-Jun 1979	Jan-Jun 1980	Index	Jan-Jun 1979	Jan-Jun 1980
Net income distributed	282.6	270.0	131	100.0	100.0
A) For personal incomes	206.8	254.1	123	73.2	68.7
B) For social service expenditure	27.5	33.4	122	9.7	9.0
C) For expansion and improvement of plant and equipment	40.7	71.9	176	14.4	19.4
D) For reserves	7.6	10.7	141	2.7	2.9

The figures on internal distribution of income indicate quite favorable tendencies which are in conformity with the goals of economic policy for this year. Relations have been established in distribution of net income which by virtue of funds for expansion of the material base [plant and equipment] of associated labor ensured the most intensive growth--index number 176.4 and about 71.8 billion dinars in absolute amount. If we add to these the funds set aside for depreciation at the prescribed minimum rate (60.8 billion dinars), we obtain the amount of 132.6 billion dinars, which is considerably more than in the previous periods.

Because of the more difficult economic situation in the world and in our country as well basic organizations of associated labor have been behaving rationally with respect to appropriation of funds for personal and social service expenditures. Personal incomes rose 23 percent and social service expenditures 22 percent, which is in conformity with the growth of economic policy for this year.

Relations of this kind in secondary and internal distribution of the income of the socialized sector of the economy and especially the very intensive growth of capital formation were involved in the 18-percent rise of the rate of reproductive capacity and the 34-percent rise of the rate of capital formation.

The level of the economy's indebtedness drops from 76.8 percent in the period January-June 1979 to 63.2 percent in the same period of this year, since the economy was able to finance a sizable portion of its expansion with its own funds on the one hand, while on the other opportunities were limited for making investments in new projects.

Problems in Financing

Working capital: The level of working capital, efficiency of its utilization and its composition have great importance in financing the process of expanded reproduction. The figures in the table below illustrate the principal forms of working capital:

	Amount, in billions of dinars			Composition, %	
	Jan-Jun 1979	Jan-Jun 1980	Index	Jan-Jun 1979	Jan-Jun 1980
Principal forms of working capital—total	883.6	1,172.1	133	100.0	100.0
Cash and securities	140.7	180.4	128	15.9	15.4
Total receivables from customers	303.1	437.7	144	34.3	37.3
Total inventories	439.9	554.1	126	100.0	100.0
Raw materials, supplies, expendable items and containers	168.0	219.1	130	38.2	39.6
Work in process	83.3	100.5	121	19.0	18.2
Finished products	61.9	72.2	117	14.1	13.0
Commercial goods	126.7	162.3	128	28.7	29.2

The figures show that receivables from customers (index number 144) have been the item in the composition of working capital that increased the fastest, and then came cash and securities (index number 128). The growth of inventories has been somewhat more moderate, and in their composition the fastest growth was shown by inventories of raw materials and containers (index number 130). These relations show that the economy's liquidity is not at a satisfactory level, since a sizable share of working capital consists of receivables from customers and inventories. This is creating problems in financing expanded reproduction.

Sources of business capital: From the standpoint of the economy's liquidity it is very important to examine the distribution of sources of business capital, since this shows to what extent the principles of pooling capital and relations based on income-sharing are being implemented, this being one of the most important elements of faster development as a whole. The figures in the following table illustrate relations in sources of business capital.

In the distribution of sources of business capital pooled capital (index number 140) had the fastest growth, and it was followed by credits for working capital (index number 126).

However, even though pooled capital showed the most intensive growth, its share in total sources of business capital is still relatively low. This

indicates that the pooling of labor and capital on the basis of income-sharing is not proceeding fast enough, and this is creating certain problems for faster economic development of the economy and for improvement of its economic position as a whole.

	Amount, in billions of dinars			Composition, %	
	Jan-Jun 1979	Jan-Jun 1980	Index	Jan-Jun 1979	Jan-Jun 1980
Principal sources of business capital—total	2,022.6	2,522.7	125	100.0	100.0
Permanent sources	1,092.8	1,356.1	124	54.0	53.8
Pooled capital	56.7	79.4	140	2.8	3.2
Credits for fixed capital	460.8	568.9	123	22.8	22.5
Credits for working capital	412.3	518.3	126	20.4	20.5

Losses Remain an Urgent Problem

Over the last several years losses in the economy have been a serious socioeconomic problem in spite of a certain reduction. The measures taken to solve the problem of losses and in particular the measures of financial rescue policy have had definite results, but their implementation is not consistent everywhere.

The causes of the occurrence of losses vary, but in the main they can be reduced to low labor productivity, underutilization of production capacities, inappropriate organization of work, discrepancy between the distribution of income and actual achievement, running from improper assignment of funds to personal incomes all the way to high obligations on the basis of interest on credits, taxes and contributions for public and social service expenditures, and so on.

The table below shows in more detail the trend of losses by the sectors of the economy:

	Amount, in billions of dinars			Composition (entire socialized sector of economy = 100)	
	Jan-Jun 1979	Jan-Jun 1980	Index	Jan-Jun 1979	Jan-Jun 1980
Total current losses	13,140.5	16,705.3	127	100.0	100.0
Industry and mining	8,522.7	10,692.7	125	64.9	64.0
Agriculture and fishing	337.9	420.3	124	2.6	2.5
Timber and lumber	26.3	26.6	101	0.2	0.2
Water management	29.8	38.2	128	0.2	0.2

Table (continued)

	Amount, in billions of dinars			Composition (entire socialized sector of economy = 100)	
	Jan-Jun 1979	Jan-Jun 1980	Index	Jan-Jun 1979	Jan-Jun 1980
Construction	324.9	571.5	176	2.5	3.4
Transportation and communications	1,189.0	1,822.5	153	9.1	10.9
Trade	356.2	303.2	85	2.7	1.8
Hostelry and tourism	1,888.1	2,292.2	121	14.3	13.7
Crafts and trades	155.2	256.2	165	1.2	1.5
Housing and municipal services and utilities	257.5	193.2	75	1.9	1.3
Financial and other organizations	52.8	88.7	168	0.4	0.5

The largest growth of losses in this period occurred in construction (index number 176), financial and other organizations (index number 168), crafts and trades (index number 165), and transportation and communications (index number 153). In the breakdown of the total losses of the socialized sector of the economy 64 percent occurred in current business operation in the sector of industry and mining, 13.7 percent in hostelry and tourism, and 10.9 percent in transportation and communications. The share of the other sectors in the total losses of the socialized sector of the economy is considerably lower. In trade and housing and municipal services and utilities the losses were lower than in the same period of last year.

All this indicates that the problem of losses, especially in basic organizations of associated labor in the sectors of industry and mining, construction, transportation and communications, and hostelry and tourism, is a very urgent one and requires much more consistent efforts at solution involving all factors, beginning with basic organizations of associated labor and running all the way to sociopolitical communities.

[Box] Encouragement and Warning Signs

On the basis of figures from semiannual statements for the period January-June of this year, compared to the same period of the previous year, we can observe that the socialized sector of the economy has achieved satisfactory results in this period in certain sectors of economic activity, as manifested in the following:

A sizable growth of gross income and income of the economy was achieved along with a more moderate growth of the physical volume of output and a more moderate movement of domestic demand;

Investment expenditures show certain signs of more moderate growth in comparison with previous periods;

Relations in secondary and internal distribution of the income of the socialized sector of the economy are considerably more favorable, since appropriations for social service and public needs increased more slowly than income, and personal incomes and funds for social services of OOUR's increased more slowly than the net income of the economy. Objective opportunities were thus created for augmenting the material base of associated labor and also raising the economy's ability to form capital and reinvest. Trends in the distribution of income and net income were in conformity with the goals of economic and stabilization policy for this year;

More favorable relations were recorded in foreign trade, since the value of exports has been growing considerably faster than imports, though the country's payments deficit is still very large.

However, in spite of these constructive trends in operation of the socialized sector of the economy, problems are still present which are frustrating more rapid socioeconomic development.

The pressure on prices is still present, which could secure ["devalue" is presumably meant] favorable results in the conduct of economic activity;

The supply of the domestic market with consumer goods is also an urgent problem that demands a more consistent solution.

The growth of losses, especially in the sectors of industry, construction, trade and hostelry, and also transportation continues to be quite marked and is a major socioeconomic problem.

We can expect the tendency of favorable results in economic activity to continue in the coming period and that the influence of the adverse trends will be considerably mitigated, especially in the domains of primary distribution and foreign trade. It is expected that the problems causing losses will be resolved more consistently.

BRIEFS

YUGOSLAV-ALBANIAN TRADE--In the first 8 months of this year trade in goods and services between Yugoslavia and Albania totaled $74 million in value, ($38.6 million in Yugoslav commodity exports, $10 million in Yugoslav services, and $25.4 million worth of imports from Albania). Problems in trade between the two countries (largely late deliveries) are expected to be overcome, so that this year's trade will probably reach $100 million to $120 million in value, or 52 percent more than the volume planned for 1980 which was $78.6 million. ROLE OF FINANCIAL ORGANS IN IMPROVING ECONOMY

Tirana RRUGA E PARTISE in Albanian No 6, Jun 80 pp 17-31

[Article by Haki Toska, member of Politburo of Albanian Workers Party Central Committee: "Let Us Measure the Perfection of the Work of Financial Organs by the Fulfillment of the Tasks for Improving the Effectiveness of the Economy"]

[Text] In the execution of directives and decisions of the Seventh Party Congress, of the tasks assigned by the plenums of the party Central Committee after the congress and of Comrade Enver Hoxha's recommendations, the financial workers have increased their mobilization and efforts to continually improve the quality of their work, and to improve the active role of finances in the economy, in planning and in executing, thus, to make an ever greater contribution, together with all the people, to the development of the economy and culture, strengthening the defense capacity of the country and improving the living conditions of the masses.

However, seeing the problems from the vantage point of the tasks assigned by the 7th Plenum of the party Central Committee and of the recent recommendations of Comrade Enver Hoxha, the further perfection of the organization and management of work remains an important task for all financial workers, at the center and at the grassroots. The issue is that all the links of the financial system should deal much better than now with the basic economic and financial problems, especially with those matters directly connected with the increase of production, with the further improvement of the effectiveness of the economy and of accumulation and with the continual improvement of monetary circulation, of the strengthening of control by means of the lek, and of the further perfection of work and management in every link of the economy.

The economy and finances develop together and in harmony. The correct understanding of this unity by all workers, especially by the workers of the financial system, requires that we use our mental and physical forces and energies on a calculated basis, with effectiveness and with profitability so that we will protect and use the lek of the people properly, so that every expenditure is carried out strictly within the

requirements of established plans, norms and laws. The implementation of the tasks in these fields to the very last, with initiative and in a creative manner, takes on a particular importance in the present and future situations, when we are building socialism in a hostile capitalist-revisionist ocean that tries directly or indirectly, with all the means at its disposal, to hamper and sabotage the building of socialism in our country.

1.

The improvement of work of financial organs and organizations is rated in accordance with the uninterrupted increase of production and of its effectiveness, constituting the sole source of our social accumulation. Financial means are entrusted by the party and government with very important functions, first of all with the task of playing their active role in increasing and mobilizing the resources of accumulation and in distributing and controlling its correct use. Precisely for these great issues, the scientific, economic and financial thought must be activated in the best way possible, dealing more thoroughly with economic processes and phenomena and keeping better in mind the requirements of the objective economic laws of socialism in every production activity and in other social activity, so that not only the general social product, but also the effectiveness of social production will be increased. "And, when it comes to the laws that deal with the effectiveness of social production," Comrade Enver Hoxha pointed out at the Seventh Plenum of the Party Central Committee, "we must be very careful, because, this is a great and pressing problem for all our economy. Effectiveness is, so to say, the result of all the factors of development of socialist production, the factors which depend on work, struggle and the efforts of all workers."

The problems of the increase and effective use of accumulation have been and are the main issues of the economic policy of the party, closely linked with the implementation of the revolutionary principle of relying on one's own forces. Our socialist state does not accept credits and aid from any capitalist, bourgeois-revisionist country. During the entire 35-year-old historical period of the building of socialism, the financing of the needs for the development of the country has been met mainly by the accumulation of our economy. The year 1979 was the first year that the state budget completely relied on our financial resources; it was successfully fulfilled. Our economy has been financed and has developed in an uninterrupted manner and at high rates. During the first four-month period of the current year, the budget revenues and other financial indicators also were, in general, well fulfilled. These victories have their foundation in the correct party line and in the heroic and empassioned work of our people.

A number of factors, linked and woven together, have influenced the increase of accumulation.

The basic factor for raising accumulation is the increase of production at high rates in all branches. In its struggle with the difficulties of growth and with the obstacles which the imperialism-revisionist encirclement is creating for us, production in our country has been continually increased and has always satisfied, in the best way possible, the needs of the country and of the people. Nevertheless, the party has drawn the attention of its organizations and of the governmental and economic organs to the fact that, in regard to this great problem, we must show more concern, because, the shortages created time after time in specific branches and enterprises cannot help but have negative consequences on the economic and financial situation of the country.

However, to increase accumulation, the reduction of expenditures for production, constructions and services has been and remains a very important factor, from which it is expected to assure the largest part of the growth of accumulation. During the first 4 years of the Sixth Five-Year plan, the majority of economic enterprises, especially those of the machine industry, the chemical fertilizer production industry, the garment and footwear industry and so forth overfulfilled their tasks for the reduction of production costs. However, opportunities and reserves are still very great. There are disturbing problems, especially in the enterprises which do not fulfill the tasks planned for the reduction of costs. Therefore, Comrade Enver Hoxha recommends that, in this field, the bull must be taken by the horns and we must carry out deep plowing.

Practice shows that efforts for the reduction of costs are not as serious as those carried out for the other indicators of the plan. And, in this field, there are important problems that concern planning and implementation, the methods that are being used and record keeping. But, there also is global fulfillment. Thus, for example, in some cases, the tasks for cost reduction in enterprises, districts and ministries are not set on the basis of a scientific work, but on the basis of some general calculations that become the reason for manifestations of subjectivism and voluntarism. In certain enterprises, this important indicator is not analyzed for every factory, department, plant and sector; while, in the clothing, glass and shoe plants we still do not have a cost for production unit; it is calculated and maintained in accordance with the level of expenditures--a fact which obstructs the expansion of the economic-financial analysis for the discovery of internal reserves, for improving the effectiveness of expenditures of work and of materials.

We have a good work experience in the evaluation and pursuit of the problems of costs, especially in the textile combine, the chemical enterprise in Durres, the cement plant in Vlore and in other places. The finance and planning economists of these enterprises are doing a good study work for planning their costs and, on this basis, they are also setting their tasks for applying them to every production link and process. In these enterprises, the cost is not considered as an indicator that concerns the plan and finance branches alone; on the contrary, all the branches, and not only the economists and the plan and financial

specialists, but also the specialists in techniques and technology, must deal with planning and with the pursuit of its execution. Under the concern of the party organizations, the cost has become the object not only of quarterly analyses, but also of monthly analyses and even more frequent analysis in all the links and fields of these enterprises. In the meantime, it has also become the problem of the working collectives.

However, people are not working with the required seriousness, especially planning and finance workers, for the generalization of work experience in these enterprises. There is still no serious effort, a work with scientific bases, to penetrate these great problems, whose solution requires technical, vocational, organizational and managerial capacities; it requires the implementation and improvement of methodology and of the methods of production costs, the direction of the scientific organization of work and harmonization of work between planners and finance workers and other specialists and cadres, beginning with the enterprises and extending to the central departments.

The problems of costs, of profitability and of socialist accumulation, it was stressed at the Seventh Plenum of the Central Committee of the Albanian Workers Party, are of vital interest for the dynamic development of the economy and, as such, they must be considered thoroughly and as a whole, from the time of planning and, later, must be monitored during their execution. Practice shows that, in the specific enterprises, plans for the reduction of costs with reserves are carried out, or that tasks for the reduction of costs are stipulated without harmonizing them with the tasks for the increase of the net revenues of the enterprises. Such cases of disharmony have also been observed in the quotas sent by the ministries for the draft plan of the Seventh Five-Year Plan (1981-1985). Various factors, mainly of a subjective nature, are responsible for such shortcomings and weaknesses; but, the planning and finance workers and economic directors at the grassroots and in departments, by the means of a detailed analysis, can and must know these factors and must exert influence more actively in those directions that bring the improvement of the profitability of the economy and the increase of resources of accumulation. Among other things, it is necessary that, within the framework of improving the methodology of planning, in addition to the tasks for the reduction of costs and for the net revenues of the enterprise, which are plan indicators, it is necessary to stipulate, give and set profitability as a plan indicator, so that the economic cadres will have this indicator as a lever of control for verifying the quality of the planning and execution of the economic and financial indicators.

Time has come for the cadres of the economy to improve their knowledge about these fields, so that they will know and master all the keys of management of enterprises and branches. Above all, it is necessary for finance workers and all specialists and other cadres to become more aware of what Comrade Enver Hoxha said--that production does not mean quantity and quality alone; on the contrary, it is a complex which includes

productivity, costs, profit and profitability, distribution and so forth. Therefore, one of the main fronts for perfecting the direction and organization of work is the struggle against one-sidedness observed in this field which obstructs the entire examination and treatment of the processes of the dynamic development of the economy.

Comrade Enver Hoxha teaches us that the "financial problems, the assurance of domestic resources of accumulation and the problems of the effectiveness of social production in the Seventh Five-Year Plan will be among the most acute problems that require a greater level of guaranty." The deep understanding of this party recommendation requires complete coordination and complete merging, in one single effort, of the work of workers and specialists in planning, finance, and technology and of other cadres with the problems of production, of distribution, of costs and of the effectiveness of social production that insure the socialist accumulation and the continual financing of our socialist economy.

The monitoring of the economic-financial activity of the enterprises which have losses and which absorb a part of accumulation demands a special attention. The analyses which have been made show that the main reason for these enterprises' unplanned losses is the weaknesses observed in the organizational and management work of the government and economic organs, especially in the work method of some leadership cadres who do not understand and do not correctly evaluate the unity between economic indicators and financial indicators and, consequently, do not struggle with the necessary concern to fulfill all production indicators with full harmony. Life gives us many examples showing that, when this problem has been correctly evaluated and handled, good results have been achieved. Thus, for example, some years ago, the meat and milk combine in Tirana used to have losses; but, when the party organization took the problem in its hands and put all its levers in motion, making the problems of production costs, losses and profitability of the enterprise the concern of the entire collective, of cadres and of specialists, the means to take the enterprise out of its backwardness and to convert it into a fruitful enterprise that gives considerable accumulation to the economy were found.

On the basis of data from progressive enterprises and the work experience of other enterprises, enterprises which used to have losses, but, which now have been converted into fruitful enterprises, there is no reason at all for some agricultural and fishing enterprises to have losses when they have a powerful technical-material base, trained manpower and so forth. Therefore, the financial workers, led by the party organizations, are involved in a serious work to implement the recommendation of the Seventh Plenum of the Central Committee of the Albanian Workers Party, that is, to re-examine and analyze with a critical eye the activity of the backward enterprises and, during this year, to establish concrete measures for improving their economic and financial situation.

Practice shows that some agricultural enterprises and cooperatives make their expenditures for machinery, fertilizer, irrigation, seeds, improvement of livestock breeding and so forth in accordance with the plan and, even, overfulfill them; while, they do not fulfill the planned tasks for increasing yields, production and accumulation. Thus, for example, last year in the agricultural cooperatives, while the revenues for 100 leks materials expenditures were increased by 15 leks more than in 1978, again the effectiveness of expenditures was fulfilled about 11 percent. The use of credits, despite the improvements that have been made, still is not resulting in the required efficiency, especially in the livestock sector. Here, the reasons are mainly of a subjective nature, linked with the failure to fulfill the production tasks, with the insufficient evaluation of financial matters and with weaknesses in the organizational and management work.

Our socialist economy is developing in an uninterrupted manner; therefore, production expenditures are also being increased. However, the issue is that every single lek spent must be calculated "with a well sharpened pencil;" we must have the lek continually under control, taking into consideration its effectiveness and aiming at increasing revenues for every lek spent, because, there are leaders who do not take into consideration the issue of production costs and how production can be fulfilled with as few expenditures as possible, or, if planned expenditures are exceeded, they do not take into consideration the fact that they should be accompanied and justified by an above plan increase of production and accumulation. The party organizations, the government and economic organs and the finance and planning workers must deal better than hitherto with these important problems, carrying out studies, analyses and uninterrupted controls and by drawing the necessary conclusions for improving management and organizational work.

In the past years, a great ideological, explanatory and convincing work has been carried out with the masses of cooperative members for a thorough understanding of the role of accumulation in our present and future conditions, as a basic resource of expanded socialist reproduction in the agricultural cooperatives. As a result, an increase of the accumulation norm has been observed in almost all the districts. The circulating funds and wage guarantee funds have been increased in many agricultural cooperatives; and the initiative of Vlore District to make advance payments not with bank credits but with the means of the cooperatives is being expanded. In this field, however, there are problems that require extended economic-financial studies and concrete measures. First of all, it is necessary that all opportunities to increase accumulation must be used, especially those from industrial crops and from the livestock and fruit growing sectors. But, along with this, it is just as necessary for the use of the accumulation fund to be kept under better observation and under a continual control, because, not infrequently it happens that the accumulation created is not used to the extent required for expanded socialist reproduction, especially for the expansion, protection and supply of the land, for the development of fruit tree growing and livestock

raising and for other purposes. During 1979, some 262 million leks of investments were not made in the agricultural enterprises and cooperatives; and what is worse, some cadres and workers consider this failure to fulfill these planned investments as a savings. Such a concept and practice has negative consequences for increasing production and improving the well-being of the masses. Deficits in investments obstruct the rates of development and compromise the fulfillment of production tasks for the future and, consequently, affect the profitability, the extent of accumulation and the revenues of the members of cooperatives. Along with shortcomings and weaknesses in the fields of management, organization and supply of the necessary material base, erroneous concepts about the role of investments prevent the proper struggle for fulfilling the plan and make them fail to make better use of the many environmental means and other internal reserves for fulfilling their plans. In these circumstances, it is necessary that the responsibility and control of government and economic organs be further strengthened, especially, of the finance and bank organs, in order to influence the complete fulfillment of the tasks in the field of investments in the agricultural cooperatives.

Last year, the financial organs made some serious efforts to participate more extensively in the economic-financial activity of foreign trade and, as a result of this, there were improvements. Nevertheless, the Seventh Plenum of the Party Central Committee recommended that the finance organs further strengthen their influence on the fulfillment of export-import plans. The task is set forth that, along with increasing goods for export and their range, they also improve the effecitveness of foreign trade. But, how can its effectiveness be improved when, in some cases, articles with high production costs of poor quality and badly packaged are being exported? These things happen because the problems of export are not considered thoroughly and as a whole by some cadres and because it is not properly taken into consideration that the profit from the goods that we export depends, first of all, on how much and how we have seen the quality, quantity and value of the goods that we export as a unit.

The quality of goods for export is one of the most acute and most complex problems, reflecting the awareness of workers, the effect of the ideo-political and organizational measures and the level of production technology and so forth. And, it is a fact that improvements in this field are significant. However, there are euphoria and self-contentment that become obstacles in the work for the further and continuous improvement of the quality of goods and of their packaging and labelling in accordance with the requirement of the times. Thus, for example, last year, Albkontrol [the bureau for inspection and control of import and export goods] blocked some kinds of goods because of their poor quality; these goods, in order to respond to the requirements for export, need supplementary expenditures which are payments completely without production; while, some other goods, also for similar reasons, are sold at low prices on the world market. Therefore, the party recommends that it is essential for its basic organizations to deal with these problems in better way;

they must exert control over the government and economic organs and ask them to report on the correct execution of the guidelines and directives given in this field. In a particular manner, export-import problems and those of currency require more concern and preoccupation and more work and studies on the part of financial and bank organs. It is important that, in regard to these problems, the finance workers operate more actively in the enterprises and cooperatives which produce goods for export and which use imported materials; they must organize meetings and talks and take measures together with production workers and cadres so that they will directly and from close range influence the improvement of work and anticipate situations, not only when everything has ended, when the damage has been done and when supplementary work and materials are needed to put the defects right.

The correct determining of investments on the basis of extensive studies and, especially the use of investments with great effectiveness, is an important field where the work of the finance workers can and must be further strengthened. The deficits that occur in the fulfillment of the investment plan and, consequently, in that of the use of accumulation and, especially, in the creation of new accumulation, show that there is no correct response to the party criticism in regard to surpluses in the planning of investments and in regard to the weaknesses in the organization of work during execution. Despite improvements, the extension of work in many projects at the same time still continues--a fact that influences, in a negative manner, the rates of construction and assembly and the quality and costs of construction. The financing of investments, too, continues to be carried out with shortcomings. In some cases, relations between investors and executors are characterized by a spirit of reciprocal concessions, or reciprocal bureaucratic obstructions are created. In Korce District, for example, after a project was completed and put into operation, the investor and the constructor, instead of settling together the financial problems that had emerged, started sending reports of many pages and of many points to each other. And, such activities, that create artificial difficulties and obstacles, sometimes to the construction itself and sometimes to the investors, which take whole months to settle because of the slowness of the financial and bank organs, exist in many districts. The task is that we must raise the economic-financial work in investments to a higher level, that more studies and analyses must be carried out, that the profit from every project in the construction-assembly sector and in exploitation must be better documented and that the extension of investments below limits must not be permitted, as happens in some districts. Everything must be carried out with calculation, pencil in hand and under strict control, correctly solving the technical-technological and economic-financial problems so that projects are put into operation as soon as possible and with full capacity. In this field there is a great deal of rich experience, such as the experience of the nitrogen fertilizer plant in Fier District, of the superphosphate plant in Lac, of the auto-tractor combine in Tirana, of the copper metallurgical plant in Rubik and so forth, where the

planned capacities have been overfulfilled and where the profitability of production has been continually improved. However, this experience must be generalized, taking into consideration the fact that production capacities, technology and profitability in enterprises are not static data, which are given once and for all; on the contrary, they change continually in the dynamism of development because of the work and struggle waged by workers, specialists and cadres for putting production on more and more scientific bases.

The effectiveness of our economy is closely linked with the increase of the purchasing power of the lek and with the continuing improvement of monetary circulation. Knowing and better implementing the requirements of the laws of the money in circulation, the government and economic-financial organs at the center and the base, under the leadership of the party organization, have made improvements in the field of planning and execution. However, the finance and bank workers, as Comrade Enver Hoxha teaches us are assigned great tasks so that they will be more sensitive to any phenomenon connected with monetary circulation and that they must not be lulled to sleep by the idea that no evil can happen to us because we are a socialist country. We must be vigilant; we must foresee the events; we must close all the paths to the possible manifestation of inflation.

In this framework, along with the priority increase of the production of the means of production, special importance is assigned to the continuing increase of consumer goods. In this field, the party has assigned a number of concrete tasks to the production enterprises, the trade enterprises and the financial and bank organs. However, the influence of financial organs on the production, distribution and circulation of goods cannot be exerted from the office nor by letters; on the contrary, it can be exerted by moving the work as near to the enterprises and cooperatives as possible, where production, assortments, quality, contracts, difficulties and obstacles that emerge, as well as the opportunities and roads to overcome them, can be seen with the eyes and touched with the hands. We stress this because many finance and bank workers do not show proper concern for fulfilling the production plans and for their distribution on schedule, for utilizing all their possibilities and domestic reserves and for increasing production and improving its quality. Let us be more anxious when we see that in some enterprises the use of raw materials and of other materials is not given proper attention on the basis of established norms and, consequently, the norms are exceeded; when we still have materials whose norms for consumption have not been established; and when the coefficients for the utilization of steel, timber and so forth are still low. Let us think hard and work with pencil in hand to prevent everything that is produced with the efforts and sweat of the people from being wasted and to further increase the range of the production of consumer goods, because, this is how we will further increase production and accumulation and satisfy more and more the increasing needs of the working masses.

The correct and economical use of the wage fund is given a particular importance, especially in the conditions of the comprehensive development of our economy. Improvements have been achieved continually, and other improvements must be made, in the field of the planning, use and control of the wage fund, on the basis of thorough studies. Nevertheless, there are still enterprises that exceed the wage fund without documenting it with production and accumulation; or there are agricultural cooperatives which do not reach their expected results in production and in revenues in harmony with the wage fund that has been consumed. The positive experience gained by some economic enterprises, where the influence of financial organs has been greater, must be disseminated in the other enterprises, especially in the agricultural cooperatives where problems in connection with planning and the correct use of the wages fund have emerged and continually emerge.

As practice has shown, the effectiveness of the use of wage fund is improved when it is seen and used in close correlation with the quantitative and qualitative indicators of production, with the perfection of the forms of compensation for work, correctly executing the requirements of the socialist economic law on compensation in accordance with the quality and quantity of work, so that the workers who work more and better are encouraged. Of course, those are matters that require thorough studies with great responsibility in accordance with the special characteristics of every branch of our people's economy. However, the correct solution, in a scientific manner, of the problems that arise in the field of the wage fund also requires more powerful and effective struggle against the manifestations of liberalism and bureaucracy observed in many cases. In some bank branches in the districts, the functions of control of the wage fund are extended up to the enterprise management and do not go further down, where the excess of expenditures has been made and where the situation can be improved. Even less do they go to the agricultural cooperatives, especially to sectors and brigades. To improve work in these fields, the finance and bank workers must play their proper role in regard to the correct execution of the socialist principles of distribution, so that wages will be earned through sweat and useful work for s ciety, preventing all the cases of irrational use of the wage fund which can become a source of many evil things of an economic and social nature and, in a particular manner, can become an obstacle for increasing the effectiveness of production. Correct relationships between production, labor productivity and the average pay of workers must be established from the time of planning and be maintained, especially, during the period of implementation.

2.

The Seventh Plenum of the Party Central Committee opened new horizons for the further perfection of the work method of finance and bank workers. The party demands that we become involved in concrete actions for perfecting organizational and management work, especially at the grassroots,

where petroleum and minerals are extracted and where machinery, equipment, spare parts, raw materials and consumer goods are produced and in the enterprises which produce goods for export; and that we pursue the implementation of our programs in a broad front, because, there are cases when our workers shut themselves in their offices and deal with paper work more than they should. The nearer to the workers, cooperative members and finance workers, who struggle at the grassroots, we go, the better the situation will be known, the more valuable studies will be carried out and the better the financial thought and the active role of all financial workers at the grassroots and the center will be. The systematic monitoring of the plan tasks requires special attention, with the organizing of a quicker and more complete system of reports on revenues and expenditures, from the enterprises, cooperatives and the sections of the executive committees of the people's councils in the districts up to the ministries.

Good experience has been gained in the monitoring of tasks by financial organs; this must be generalized and further expanded; however, there still is superficial work, especially in some districts. Thus, for example, the financial sections of the executive committees of the people's councils of Tirana, Berat and Kolonje districts and the finance directorate of the Ministry of Light Industry and the Food Industry work much better than the finance sections of the executive committees of the people's councils of Elbasan, Fier, Librazhd and Tepelene districts. The effectiveness of credits is better evaluated by the Durres Bank than by the Korce Bank. The financial organs of the Vlore District study and solve the export problems better than those of Lushnje and Mat districts. The social security branches in Elbasan and Mirdite monitor temporary work disability much better than the Tirana, Gjirokaster and Diber branches. The agricultural banks in Tirana and Gjirokaster monitor the use and banking of credits in agriculture much better than those in Kruje and Shkoder and so forth.

The improvement of scientific direction and organization requires, first of all, the further perfection of financial planning. On the basis of experience gained, the quality of financial plans has been continually improved; and serious efforts are being made to better and better coordinate the financial indicators and other economic indicators of production. But, in this field, much remains to be done, especially in regard to the drafting of a scientific and mobilizing plan, discovering all the reserves and planning their complete activation, because, only where the plans are tight, Comrade Enver Hoxha teaches us, are mobilization, struggle and efforts of workers, and their successes, greater. The opposite takes place where plans with reserves are drawn up. In particular, attention must be given to the drafting of tight plans for costs, for product on and for quality and for the other qualitative indicators of the plan, because, they will become a lever of encouragement in order to vitalize and strengthen work in enterprises and cooperatives.

To avoid cases of setting tasks lower than the real possibilities that these indicators have, it is essential that, when planning them, we rely on the progressive average, on the experience of advanced workers. However, to avert formalism, subjectivism and voluntarism in this issue, it is necessary that we study the progressive experience extensively and discover the ideological, political, technical and organizational factors that have led to the achievement of high results and, on this basis, the concrete measures must be established in accordance with the conditions of every economic enterprise, agricultural cooperative and state institution. The driver Dhimiter Delijorgji made extensive changes in using motor fuel sparingly, in the technical-utilization indicators of his vehicle and in prolonging the life of his vehicle. Lida Thomo, a teacher in the Agricultural Institute in Korce gave a distinguished example in the application of mathematics in the economy. Ollga Konomi, a worker of the Stalin textile combine in Tirana, became the initiator of a whole movement converting temporary disability to permanent work ability. But, such examples that tell about the high awareness of our people educated by the party, about their inspiring and passionate work and about their minds and golden hands, that can create wonderful things, are found everywhere. The financial workers should not only record these precious morals and material values; the main thing is that they should devote all their capacities and exert all their influence so that it is planned on the basis of these successes. "The active role of the plan and of finances," Comrade Enver Hoxha stresses, "would appear even greater when it includes, as tasks of the plan, the best achievements of advanced workers and of the progressive working brigades within the enterprise and the cooperative and outside them as well."

Coordination, from the time of planning, of economic indicators of production and the financial indicators is a problem requiring continual attention, because any change carried out in economic indicators of production, without being accompanied by relevant changes in financial indicators, would create disharmony and would bring anomaly to the production process and financial activity. Cases of superficial work and failure to reflect in the financial indicators the changes made in the economic indicators were also observed during the work for drafting the 1980 plan. In regard to such manifestations, first of all, the financial workers, from the control departments and districts down to the grassroots workers, in the economic enterprises, agricultural cooperatives and in every unit of social production, must find their own responsibility.

An erroneous tendency, which must be fought more vigorously, is that of setting more pressing tasks for the last quarter of the year. Thus, for example, the planned accumulation in the second half of last year was 18 percent greater than that of the first half. Despite improvements, this problem, in some cases also appears in the plan of this year. However, such work practice becomes the cause for creating an unjustified euphoria in the first months of the year, and later on weaknesses and irregularities are created in the execution of economic-financial tasks.

This is why, it is necessary for the financial organs to work with more responsibility during all the phases of planning and implementation, struggling against any manifestation of formalism.

In the field of planning and implementation in general, and also in the financial field, important problems arise in regard to the execution of the party line, such as, for example: How much are the plan targets being explained to the workers and cooperative members? How is the opinion of the grassroots workers taken into consideration by the state organs in the districts and how is the opinion of the district state organs taken into consideration by the central ministries? Do they develop debates so that one link can convince an other link through arguments, or, under the pretext that "there is no time," are changes made in an arbitrary manner by the higher organs? Is there a principled struggle, or are compromises made, such as, "you let go a little, so that I also can let go and, thus, we arrive at the same idea, together, in order to avoid headaches," as happens sometimes in the course of discussions between the ministries and the sections of the executive committees of the district people's councils.

These are problems of an ideo-political, economic and organizational nature that deserve a greater attention than they have received so far so they can always be solved with party-mindedness. The finance workers, like the planning workers and all specialists and cadres, must always give their opinion on every economic-financial problem, relying on the party line, on the study of phenomena, on the economic laws and on our revolutionary law, giving importance to revolutionary debate, as a means that expands and further improves work, the economic-financial thought and studies and that discovers and solves the contradictions that arise on the road to our socialist development. The party recommends that we be top revolutionaries, always on the attack. Correctly and consistently developing the class struggle, let us not be satisfied with small plans in production, accumulation and exports or with keeping manpower above the plan or with having expenditures without production; and let us not tolerate the cover up and softening of attitudes toward cases of violation of the law, cases that are discovered by the control-review process. We must allow with anything that contradicts the financial policy of the party.

On the basis of the party directives, work continues everywhere for the drawing up of the draft of the Seventh Five-Year Plan, a plan that fully relies on our own forces. For the first time, in this five-year plan, the financial indicators will be discussed and drafted in detail along with the economic indicators. This is a great and responsible task for all finance workers; it requires a total mobilization, knowledge and precision for planning the state financial and monetary resources and for a distribution of these funds as wisely as possible, with profit and with precise calculations.

One of the main characteristics of the new five-year plan, which is being drafted, is the harmonization, the organic relationship of the economic aspect with the financial aspect of the plan, meaning that the process of the drawing up of the draft plan will unite the economic indicators and the financial indicators, doing this work at the same time, with the same reliability and with responsibility. The correct understanding and execution of this unity by the state and economic organs in general and by the financial organs in particular will make it possible to avoid cases when extensive operations to increase revenues and to reduce expenditures are made at the center. These operations must be carried out on schedule in the economic enterprises and agricultural cooperatives, where the resources of accumulation are produced and the reduction of expenditures takes concrete form. The party has stressed that the guiding quotas for the monetary and hard-currency revenues should be considered as a minimum and that, during the discussions and drawing up of the plans, they must be increased, discovering the internal reserves which our socialist economy has and continually creates; while, the guiding quotas for the monetary and hard currency expenditures must be considered as a maximum limit and that efforts must be made to reduce them by finding ways to strengthen the system of savings. It is precisely in these fields that it is necessary for the economic and financial ideas of our cadres to be elevated higher by implementing the criteria, methods and methodology of our socialist planning more broadly and more thoroughly, especially in order to execute the tasks assigned to us by Comrade Enver Hoxha's recommendation that only by the means of a most scientific and most tight planning would it be possible to implement the party directives on the improvement of the effectiveness of the economy and on the increase of material, financial and hard currency reserves.

In strengthening the dialectical unity between economic and financial indicators, both in planning and in implementation, an important role is played by the 10-day and monthly economic and financial analyses in economic enterprises, agricultural cooperatives, in districts and ministries, including data not on the books. These analyses, which must be used in discovering and analyzing the concrete economic and financial phenomena, the relationships between economic and financial indicators, weaknesses and shortcomings and their causes and determining the measures that should be taken, will also serve as schools for increasing the knowledge of cadres and of the masses for managing the economy and as schools for learning the requirements of the objective economic laws of socialism.

In the enterprises, agricultural cooperatives, the executive committees of the district people's councils and ministries, the party has brought in and trained new cadres, and will continually bring in and train new cadres that distinguish themselves by their work, management and administration--such as engineers, agronomists, economists and others. But, in order to properly execute the tasks entrusted to them, these comrades must work more and with determination to extend their knowledge in accordance with the new tasks entrusted to them in their trusted functions.

For example, how much does an engineer or economist know about the economy and finances and how much do they know about the science of management of the enterprise or of the cooperative they are managing? Likewise, the question is asked: how much does an economist know about agrotechnology, techniques and technology? It is through economic and financial analyses, when these problems are debated, in their complexity, in sessions in which all cadres and workers participate, that people learn how to manage and to administer, therefore, how to hold the keys of the management and organization of the economy. However, in the present stage, the time has come to think better about and better execute the work forms for improving the economic and financial knowledge of cadres and the masses, such as the courses with and without interruption of work, to be attended by brigade workers and persons in charge of sectors, work centers and plants, directors of enterprises and chairmen of cooperatives and so forth. There is no scientific management of the economy without a knowledge of finances, just as there is no scientific management of finances without knowledge of the economy.

The solution of the problems, that emerge every day from the development of the economy, requires the continuous improvement of the level of training of workers of the financial system. The initiation of a postgraduate course is a good thing; but, this is insufficient. Therefore, measures have been taken to start such courses not only at the central level, but also in the districts, in order that all the workers of the financial system will be able to supplement and enrich their financial knowledge every 4-5 years. Within this framework, tasks are also set for the training of youths and students who are attending schools with or without interruption of work. This problem is also very important for the workers of the financial system who do not have the necessary vocational education, using different work forms, such as seminars, consultations for special problems, schools of progressive experience and so forth.

The administration and preservation of socialist property have always been and remain in the center of attention of finance workers. The party sets, as the main task, the implementation of preventive measures for the protection of property against appropriation, bad administration, damages and abuses. Of course, in regard to this, priority has been given and must be given to the educational work and to the knowledge of the laws by workers; but, of no less importance is the perfection of the record keeping that accompanies the movement of property and the perfection of other organizational and administrative measures, on the one hand, so that the workers themselves will protect socialist property and, on the other hand, to close the gaps as much as possible through which the abusers and damagers of socialist property might infiltrate. Within this framework, it is necessary to strengthen control over production and distribution by the means of the lek and over any work process by making calculations with a pencil in hand and by comparing material assets according to their weight, number and value and by noting the differences

and their causes. However, these controls are not the task of the examiner or the auditor alone, as some people may think; on the contrary, they are the task of all those who are entrusted with the organization and management of production in the brigade, unit, sector, plant, enterprise and cooperative, of all those who carry out the work processes and of the worker, cooperative member, brigade worker, examiner, auditor, agronomist, engineer, brach leader and of the director and so forth. The party demands that he who produces and manages must also examine. Of course, in this field, the specialized organs of the control-review department and the worker-peasant control, led by the party organizations, have special tasks with great responsibility.

Our working masses, under the party leadership are tackling the job with great revolutionary spirit so as to fulfill the 1980 plans; and, in general, the results achieved so far are good. The finance workers, as the Seventh Plenum of the Central Committee of the Albanian Workers Party has recommended, are required to work with taut nerves, to totally mobilize their mental and physical energies and coordinate their activities with all the governmental and economic links. Let us take into consideration the fact that we had failures in fulfilling the plan in some economic and financial indicators during the past five-month period. Therefore-it is necessary to correctly understand and correctly implement Comrade Enver Hoxha's recommendation that finances must have great assurance of accumulation; and this must be reached not only in the drafting of the Seventh Five-Year Plan, but also in the fulfillment of the plan tasks for 1980, the last year of the Sixth Five-Year Plan. The issues of increasing production and accumulation and the continuing improvement, at high rates, of the effectiveness of the economy are the capital problems of the economic policy of the party; their implementation requires the further pefection of the management and organization of work by the party organizations and by state, economic and financial organs.

IMPROVED TECHNOLOGY NEEDED IN CONSUMER GOODS PRODUCTION

Tirana RRUGA E PARTISE in Albanian No 6, Jun 80 pp 32-40

[Article by Shaqir Prizreni: "Perfection of Techniques and Technology in Consumer Goods Production--an Important Field of the Technical and Scientific Revolution"]

[Text] During the Sixth Five-Year Plan, our people, confronting and overcoming the difficulties of growth and the many obstacles created by the capitalist and revisionist encirclement and blockades, by complicated international situations and circumstances, have made important steps forward in the building of socialism of the country. Especially important are the achievements in the further invigoration of our socialist economy and in the improvement of its independence and self-sufficiency. During this period, many acute economic and social problems were solved. The study, designing and construction of many important projects by our people in the branches of the economy and, especially in industry, and the completion and putting into operation of dozens of projects, which were abandoned and sabotaged by the Chinese revisionists, are a living proof of the vitality of our socialist economy, of the awareness and creative capacity of our working class and people's intelligentisa, of the life-giving force of Marxism-Leninism and of the correctness of the economic policy pursued by our party.

Our party, relying on the objective economic laws of socialism, on Marxist-Leninist ideology and on Comrade Enver Hoxha's teachings, in accordance with the concrete conditions prevailing in our country and with the international situations, has built and is implementing an economic policy on the basis of which the development of the different branches of the economy will be carried out in established relationships and in full harmony between them. It is true, for example, that in the party policy for the socialist industrialization of the country, priority has been given and is being given to the development of the industry for the production of the means of production, as the main supporting base for the development of all economic branches and to the invigoration of the defense capacity of the fatherland. However, in full harmony with this, the rapid development of the other branches of the economy and, within

this framework, the development of the consumer goods industry, have never been underrated, so as to satisfy more and more, in quantity and in quality, from a revolutionary point of view, the always increasing needs of the people and of the economy for products of this industry. This fact is proven by the 35-years of activity after the liberation.

During these decades of the people's government, the overall industrial production increased more than 125 times, while that of light industry and the food industry increased about 75 times. And, if we take into consideration the fact that in the structure of the overall industrial production before the liberation the products of light industry and the food industry accounted for about 70 percent of the overall industrial production, then, the rapid development of this industry during these 35 years is more apparent. Now, our light industry and food industry is a multi-branch industry, mainly relying on the processing of the raw and auxiliary materials of the country and, first of all, on the products of our socialist agriculture. As all our industry, the consumer goods industry is a new industry, created on the basis of advanced techniques and technology of the times. It is meaningful that our country, which before the liberation used to import almost every industrialized article, today not only satisfies more than 80 percent of its needs with products from our industry, but even exports some of its goods, thus, guaranteeing considerable hard currency in revenues.

However, in spite of the great and rapid progress in the development of the light industry and the food industry, in order that the increasing needs of the masses will be satisfied in the best way possible and the production of consumer goods will cover the purchasing power of the population in best way possible, the party has assigned the tasks so that this branch of our socialist industry will undergo a further quantitative and qualitative development, especially in the coming five-year plan. The fulfillment of these tasks requires that the working people of light industry and the food industry, and workers, technicians, engineers and specialists in production enterprises and scientific-research centers think and work better than upto now in order to know, analyze and implement the directives and guidelines of the party and further perfect their style and work method, mainly dealing with the key problems of the development and modernization of this industry, correctly and most effectively utilizing the great opportunities that the party has created for the further development and expansion of the technical and scientific revolution; and, in this important sphere of social production, especially in those main fields where problems requiring solution are more acute and, aiming at discovering and using internal reserves in the best way possible, they must think and work better for improving production capacities, for the complex and judicious processing of raw and auxiliary materials and for improving the quality of products and so forth.

In the present conditions, the continuing perfection of existing techniques and technology of the consumer goods industry and the gradual introduction, in a studied and organized way, of modern techniques and

technology constitute the basic directions of the development and expansion of the technical-scientific revolution in this branch of the economy.

We stress this not because little has been done in this field; on the contrary, from one five-year plan to the other, there have been reconstructions, expansions and technical-technological improvements in the existing lines, departments, factories, plants and combines, as well as new constructions, in this industry. And, in these expansions and reconstructions and in these new constructions, the new techniques and technology have been continuously replacing what has been "out-moded" by the time; mechanization of the work and production, processes has been improved and automation and chemical, thermophysical and biochemical processes and so forth are being introduced at a more and more expanded level. However, it is a fact that, despite the continuing invigoration of this branch of the industry, still it does not always and properly respond to the quantitiative and qualitative requirements of the people and the economy, and to the requirements of exports. The food and light industry enterprises are not always in a position to "absorb" and process, rapidly and without waste, all the agricultural and livestock products. Despite the technical and technological changes carried out in the canned goods and sugar products, leather shoe ready-made clothes, and glass and ceramics factories and so forth, their level of mechanization and automation is still low in comparison with some other new branches of industry, such as the electrical, chemical, and machine branches and other branches; the technological processes are getting out-moded in some cases; and, in some other cases, there are some artisan forms of work and of production. As a result, in these branches of light industry and the food industry, labor productivity is still relatively low, the quality of goods does not fully respond to the requirements of the times and the norms for the consumption of goods and for raw and auxiliary materials are high. All this results in the fact that the goods of these industries are produced at relatively high costs and also results in the failure to produce the necessary accumulation, and some enterprises of this industry even create a "heavy burden" for our economy, in general. Therefore, the further development and extension of the technical and scientific revolution in the sphere of production of consumer goods has become an essential requirement and has a very large field of action.

In regard to technical progress in the enterprises of light industry and the food industry and in regard to the implementation of techniques, technology and most advanced methods of work organization in production, it is necessary that all be interested, whether they are simple workers or specialists and cadres of production and of the scientific-research institutions, in finding the best means, according to requirements and concrete conditions, with the foremost aim that every advancement in techniques and technology will not only be socially necessary and technically feasible, but also economically profitable, in harmony with the requirements of the principle of relying on one's own forces. These requirements are the foundation of every study and design for the technical and technological perfection of the enterprises of the consumer goods industry.

On the basis of the concrete conditions and possibilities and the present stage of development, the main directions assigned by the party for the perfection of techniques and technology in the consumer goods industry are: first, the most rapid transition in some enterprises from the artisan phase to the organization of mass production by specializing production within the unit, plant, or production center in general, by increasing the coefficient for the complex utilization of raw and auxiliary materials and by mechanizing the work processes which, presently, are done by hand. Second, the passage of production from the existing situation, a situation with stabilized techniques and technology, but relatively backward in some enterprises, to a new and more advanced situation, in accordance with the higher level that has been achieved in the units, plants, and workshops with similar processes. Third, the application of the best achievements of science and of advanced technology, theoretically documented and realized in practice on the national and international level in one established branch or sector of production for the perfection, in their totality, of work means and production processes.

It is understood that such levels of transforming processes, to be achieved through the expansion of the technical and scientific revolution, cannot be reached everywhere at the same time and, especially, in their highest level. As everywhere else, in this sphere of social production, this transformation will be carried out on a well studied and well organized basis, within the limits allowed by our possibilities and circumstances, gradually and in accordance with the concrete conditions where it will be carried out. Priority is given to the solution of those links which are more acuite and which cause more disturbance to the unit, plant or enterprise, always pursuing the principle of relying on one's own forces, a fact which does not mean that we should not profit from the experience and from the achievements of science and technology in the other countries through the utilization of foreign literature and the specialization of cadres outside the country even, to the extent of bringing, from abroad, machinery, complete lines and advanced technology when the latter is necessary, especially in the case of the production of a product for the first time, for which the necessary experience is lacking. And, within this framework, the first place is initially taken by the problems that deal with the increase of the productivity of social labor through the improvement of the level of mechanization with our domestic possibilities in order to replace manual labor at the highest level, especially in such work operations which are similar for all industrial branches, such as those of the loading and unloading of raw materials, of auxiliary materials, of ready made products and of the remnants of production, as well as their internal transportation. Also, it is necessary to replace, as soon as possible, some mechanical and physical processes with periodic activity, such as, for example, the processes of washing, cleaning, filtering, filling, packaging and labelling in the food industry and the processes of cutting and assembling in the shoe industry, the machine industry and the electrical machine industry. Preparatory operations of dyeing and stiffening in the leather and textile industries and so forth

can be replaced with uninterrupted processes, by introducing more and more elements of automation, especially in the control and direction of the processes for facilitating the work of people and for the possible elimination of subjective factors in the application and interpretation of the best parameters of established processes.

Because of the work done for applying the guidelines of the party in these fields, a good experience has been gained. Thus, for example, along with the work carried out for extending the processing capacities of the sugar plant in Maliq, by our own forces, many technical and technological improvements were achieved, further increasing the level of mechanization and automation in comparison with the situation of the existing plant. In the food industry, the use of clean crops is being intensified, and the biochemical and microbiological processes are also being intensified in the production of yeast for the bread, dairy products, wine, beer and alcohol industries, and so forth, which increase labor productivity, the level of utilization of raw materials and the quality of products. The application of some physical-chemical processes has also improved the effectiveness of refining oils, of crystallizing sugar, and of dyeing textiles and so forth. However, these processes must be applied in a broader way to the drying of food products by the means of the use, especially, of the techniques of drying by vacuuming, by corrugated layers, infra-red rays and so forth. It is necessary to work more seriously on experimentation with processes of preserving food products by means of antibiotics and radioactive izotopes and so forth. Of course, all this cannot be done easily and immediately. A wide path must be opened to the expansion of the technical and scientific revolution in these fields by struggling, among other things, against the restraining concepts of certain cadres and workers and some specialists that, allegedly, the use of such advanced processes on a large scale belongs to a remote future. The pace at which the science and technology of production are developing and the needs for consumer goods set forth the requirement for the use, at a wider and wider level, of new processes and methods. Studies, research-works and experiements of this nature must find more space, especially in the annual and future themes of the study and research centers, such as the Institute for Chemical-Technological Research.

The party has assigned the task that, along with increasing the level of the complex and rational utilization of raw and auxiliary materials, the opportunities must also be found to replace the deficient raw and auxiliary materials with other materials and to find the way to replace those which we continue to import such as, for example, hides, cotton, synthetic fibers, natural rubber and plastics, organic acid and dyes and so forth, and to replace them with domestic materials. In this field, too, the technical and scientific revolution has a very broad field of action. The main thing is that the possibilities that have been created and the considerable funds that have been allocated for their production, in imitations or as actual products, must be utilized in the best way possible, on the basis of the further development of biosynthetic processes

or of organic synthesis. However, the important task of our workers, specialists and scientists in production and study and research centers is, along with providing these products in the country, to discover the most technically suitable and most economically profitable ways of using and processing them, by utilizing the existing production capacities or by creating new capacities. This is very urgent, especially in the textile and knitwear industries, so that, with the existing stock of machines and by carrying out the necessary adaptations, clothes with a mixture of wool and "terital" fibres, cloth with a mixture of cotton-polyester and so forth, will be produced not only to compensate for the lack of natural raw materials, but also to increase the range and quality of their products.

Natural relationships and dependency exist between techniques and technology. Under established conditions, they help in the development and perfection of each other. Therefore, it is essential that any improvement carried out in technology must be harmonized with the perfection of techniques and vice versa, both in the simplest production units and in the most complex workshops.

It is known that such advanced technological processes as, for example, the homogenizing of fruit juices or of food for breat-fed children, the compression of carbonic gas that is formed in the processes of fermentation, separated distillation, hydrogenization of vegetable oils, and the processes of thermofixation and of preshrinking and so forth cannot be implemented in the conditions of low technology with ordinary work means. Likewise, it would be paradoxical to apply out-moded technological processes to completely automatic lines. If such a thing is allowed, modern technology would be converted into an "ornament," stripped of its functional aspect; we would have unilateral and partial developments and disharmony which obstruct the synchronization of production processes and, consequently, the effectiveness of social work would not be elevated to the required level nor to the level of the existing possibilities. "There is no justification," Comrade Enver Hoxha teaches us, "for placing a modern machine or a modern line in a work place, and for an established operation, at a plant or at a unit, with high productivity, when it is not accompanied by new organization of work, by the level and culture of production and by the capacities of the other links, because, in these conditions, these links become a bottleneck with all the anomalies that stem from this."

This is why the perfection of techniques and technology and the introduction, on a broader and broader scale, of the latest achievements in production are closely linked to and directly dependent upon, among other things, the level of the management and of scientific organization of work.

It is a fact that, in some branches of light industry and the food industry there still is a disharmony between the pace in increasing production and the pace of improvement of techniques and technology. It is disturbing

that, in some branches of production, for example, in the canned fruit and vegetable, alcohol and cold drinks, and hide and shoes, ready made garments industries and so forth, of unified technological processes are not applied everywhere in all their enterprises although they have the same type of production, nor are the necessary efforts made to unify them, on the basis of the best achievements, studies, experiments and implementations on the industrial level; and, this negligence and carelessness is reflected in certain cases even when reconstructions, extensions and new constructions are carried out.

The technical bureaus and the study-design work groups in enterprises and research centers have not yet properly tackled this problem with all the necessary seriousness. In their study work and, especially when it comes to carry out their design and decision, not infrequently one can observe the tendency to choose the "shortest" way, the way that causes less trouble and which, in its exterior appearance, seems to be most "profitable," and copy the ones which is the simplest and the easiest to make without bringing any improvement to it at all; the fact that its technical, technological and economic-financial production indicators are low does not disturb them at all. Thus, for example, this is what was done in the food industry for the construction of some plants for milling flour, for the extraction of oils, for the production of sauce and for the drying of vegetables and so forth, instead of taking, as a model, the flour plants and the plants for the production and refining of sun-flower oil and for the extraction of sauce in Lushnje, Fier, Elbasan, Vlore and other districts, which have a more advanced technology and, later, on this basis, introducing the new elements of techniques and technology that have been achieved in the other countries.

A typical case of superficial study--the unsatisfactory results of which have not yet served as a lesson--is that of the extension of the vegetable drying industry. During the past 10 years, in accordance with the party guidelines for improving vegetable processing, drying lines have been built almost in every district of the republic, building them as near to the raw material as possible. Considering that in this field we had to deal with the beginning of a new production, it would have been very profitable for these lines to be designed and built on the basis of the most advanced techniques and technology, in accordance with the best requirements of production and of export. But, this was not done. Starting the easiest way, mistakes were made in the selection of technology. And, failing to draw lessons from the past mistakes, the routine continued and was repeated later on, when the need arose to improve the effectiveness of production in vegetable drying lines. Instead of making this improvement on the basis of the extension of the existing lines by bringing into them the most advanced elements of techniques and technology, that required less expenditures, new lines were built with the same technology within the same enterprise, repeating the same work operations and using the existing equipment and machinery.

As a typical example of this research work, technical, technological and organizational weakness, is the case of the "Ali Kelmendi" food processing combine in Tirana, where, within the past 6-7 years, 4 special lines for vegetable drying were built and put into operations one after the other, each having the same production capacities and the same techniques and technology, with 3-4 times more expenditures for their building and assembling and with as much expenditures for production, manpower and so forth. This problem could have been best solved when the task was assigned to double the production capacities on the basis of extending the technical-technological processing of the first line. But, this required more extensive studies, experiments and the use of advanced experience and advanced achievements in this field. However, had it been done in this way, not only would much less expenditure would have been needed for the reconstruction and expansion of the existing line, but also 90 percent of the duplicate operations could have been averted, the level of mechanization and of technology would have been improved and the production expenditures would have been decreased and the quality improved.

The reasons for these weaknesses is to be found not only in the insufficient efforts carried out by the party organizations and leadership organs of this enterprise to undertake and complete such a study, but also in the partial study and the failure to choose the best solution for this problem by the Institute for Chemical and Technological Research and the Institute of Construction Designs for the creation of the so-called "model line" for vegetable drying which was characterized not only by its partial mechanization of work processes, but also by the complete lack of opportunity for future expansion. The clear-cut "decisions" of the Executive Committee of the Tirana District People's Council and of the Ministry of Light Industry and the Food Industry have also influenced these new constructions, starting with the incorrect idea that "let us first overcome the situation, later we see and act."

The selection of a model for reproduction to replace an out-moded one, with limited production capacities and with low technical and technological indicators which, in its complex, creates a semi-artisan technical and organizational situation, with many work operations by hand, is the consequence of a superficial study work. The argument that they were made for constructive simplicity and for the urgent needs of production are groundless. Referring to these problems, Comrade Enver Hoxha stressed that "the passing from the artisan phase to the field of organization of work and production requires a broader conception and a more organized struggle. Today, this issue constitutes one of the great reserves for increasing production and labor productivity. The completion of studies and the adoption of concrete measures in this field are of great effectiveness and less expensive.

Undoubtedly, in the field of techniques and technology, the perfection of the organization of production is closely linked with the expansion of the technical and scientific revolution, because, new techniques

and technology can give the greatest results if they are used on the basis of a new, adequate organization of production.

In all these directions, always promoting techniques, technology and organization of production, a broad field of study and of implementing work is assigned to all elements of production and management at the grassroots and the center and to the scientific institutions, especially the Institute for Chemical-Technological Research. These problems must take the place they deserve in their themes, especially in the content of studies, designs or dissertations, because, it is in this way that their scientific value increases and the implementation of these studies becomes more useful for our socialist economy.

In all the cells of production and scientific research institutions the people have worked and are working to draw up the draft 1981-1985 Seventh Five-Year Plan. The fulfillment of the pressing tasks that are stipulated in the field of increasing the production of consumer goods at a high pace will further increase the mobilization and feeling of responsibility of the workers of light industry and the food industry toward the people and the party in order to tackle the expansion of the technical and scientific revolution with increased forces, for the implementation of the tasks linked with the satisfaction, better and better, of the increasing needs of the people and the economy with consumer goods, in the necessary quantity and assortment, less expensively and with higher quality.

TWO YEARS OF ECONOMIC EXPERIMENT EVALUATED

Prague STATISTIKA in Czech No 7, 1930 pp 289-297

[Article by Jaroslav Vacha, Federal Office of Statistics, Prague: "The Second Year of the Experiment in the Management of Efficiency and Quality in Industry"]

[Text] 1. Evaluation of the Results of the Experiment for 1979

In 1979 the Comprehensive Experiment In Efficiency and Quality Management was carried out under economic conditions markedly different from those of the preceding period.

The shortages of electric power experienced in 1979 were the major reason for production shortfalls and the resulting failure to fulfill production plans throughout the industry.

At the beginning of the second year of the experiment the VHJ's participating in the experiment had to deal with substantially more demanding economic tasks since the production shortfall was reflected in other areas, smooth the flow of supplier-customer relations was, in particular, being affected.

Production shortfalls resulted from these causes in all the VHJ's participating in the experiment, but in the course of the year the majority of the VHJ's were able to make them up. Consequently, the unfavorable situation with respect to the formation of resources at the beginning of the year had only a partial effect on the annual results and was evident only in a somewhat lower fulfillment of the plan in the areas of economic results and marketing as against 1978. The plan for the basic indicators of efficiency and quality was, however, not affected.

In this direction, the experiment indicated that its rules make it possible, even under difficult economic conditions, to respond more rapidly to problems as they arise and handle possible difficulties that may occur and, in some cases, to limit their adverse effect on management.

The focal point of the experiment in verifying the new system of plan indicators is the financial indicators with return on production assets leading the list.

The VHJ's participating in the experiment are devoting special attention to fulfilling the plan for this indicator, since it is also the major criterion for the wage incentive system.

In 1979, 10 of the 12 VHJ's participating in the experiment surpassed the planned level of return on production assets. Overall, the planned profitability was exceeded by 3.5 percent.

The creation of profit played an important role in fulfilling and exceeding the plan for return on production assets.

In 1979, 10 of the VHJ's in the experiment exceeded the planned profit, overall fulfillment was 103 percent, the creation of profit rising 19.1 percent over 1978. The planned profit was exceeded by those VHJ's in the experiment that focused to a greater extent on innovations in production, primarily as a result of preferential pricing.

Table 1. Evolution and Fulfillment of the Plan with Respect to Selected Indicators for the VHJ's in the Experiment for 1978 and 1979

	Měrová jednotka (1)	Prováděcí plán 1979 (2)	Skutečnost 1979 (3)	% plnění plánu 1979 (4)	% plnění plánu 1978 (5)	Index 1979 – 1978	Index 1978 – 1977
Vlastní výkony (6)	mil Kčs	41 563	42 282	101,7	102,2	107,8	108,0
Hrubá výroba v cenách k 1.1. 1977 (7)	mil. Kčs	98 028	98 448	100,3	100,7	104,8	106,0
Finální odbyt celkem (8)	mil. Kčs	37 376	38 370	102,7	104,7	105,4	108,2
Objem dodávek ve VC pro: (9)							
– investice (10)	mil. Kčs	4 017	4 629	115,2	126,3	100,6	118,7
– vnitřní obchod (11)	mil. Kčs	11 292	11 362	100,6	101,1	104,2	109,5
– vývoz do S Z (12)	mil. Kčs	12 658	12 881	101,8	104,3	105,3	103,5
– vývoz do N S Z (13)	mil. Kčs	9 409	9 498	100,9	100,8	109,7	108,4
Průměrný evidenční počet pracovníků (14)	osoby (15)	430 951	430 782	100,0	99,7	100,9	100,7
Produktivita práce z vlastních výkonů (16)	Kčs	96 565	98 274	101,8	102,5	106,8	107,3
Produktivita práce z hrubé výroby (17)	Kčs	227 469	228 533	100,5	101,0	104,0	105,3
Průměrná měsíční mzda pracovníka (18)	Kčs	2 568	2 586	100,7	100,6	103,5	103,4
Rentabilita k výr. fondům (19)	%	10 84	11,22	103,5	106,7	×	×
Rentabilita k nákladům (20)	%	13,73	14,18	103,3	106,0	115,5	114,1
Podíl celkových nákladů na upravených výkonech (21)	%	87,99	87,66	99,6	99,7	98,4	98,8
Podíl materiálových nákladů na upravených výkonech (22)	%	65,81	65,71	99,8	99,5	98,5	98,0
Zisk (23)	mil. Kčs	12 791	13 177	103,0	106,1	119,1	119,2

[Key to Table 1]

(1) Unit of measurement
(2) Implementation Plan, 1979
(3) Actual, 1979
(4) Fulfillment of the 1979 plan, in percent
(5) Fulfillment of the 1978 plan, in percent
(6) (Labor) value added
(7) Gross output at 1 January 1977 prices
(8) Total final sales
(9) Volume of supplies at whole prices for:
(10) Investment
(11) Domestic trade
(12) Export to socialist countries
(13) Export to nonsocialist countries
(14) Actual average number of workers
(15) Personnel
(16) Labor productivity based on value added
(17) Labor productivity based on gross output
(18) Average monthly wages
(19) Return on production assets
(20) Return relative to expenditures
(21) Percentage of total costs to adjusted output
(22) Percentage of material costs to adjusted output
(23) Profit

All aspects of this type of price incentives were fully taken advantage of by 11 of the VHJ's in the experiment whose number of preferentially priced items increased over last year. Overall the advantage derived from preferential pricing in 1979 reached Kcs 810 million, or 45.6 percent more than in 1978.

The greatest advantage of preferential pricing was achieved by the participating VHJ's under the CSR Ministry of Industry, namely Vlnarsky Prumyal Brno, Kcs 305 million, and Pisek Pletarsky Prumysl [Knitting Industry], Kcs 139 million. In VHJ's in the engineering industry these include the Tovarny Strojireske Techniky in Prague, Kcs 120 million, and Zavody Vseobecneho Strojirenstvi in Brno, Kcs 76 million.

On the other hand, the amount under penal price reductions dropped Kcs 4 million from the 1978 figure, and amounted to only Kcs 18 million.

In addition to preferential pricing, the creation of profit was also affected by costcutting, primarily at those participating VHJ's that as a consequence of less innovation were not authorised the greater number of preferentially priced items.

The ratio of total costs to adjusted output achieved was 0.33 of a point lower than the annual implementation plan figure and 1.47 points lower than the actual figure for 1978. At the same time, the proportion of material costs in adjusted output was also 0.10 of a point lower than the annual implementation plan and 1.000 points lower than the actual figure for 1978.

A total of nine participating VHJ's had better results in terms of costs than assumed by the annual implementation plan.

For individual VHJ's participating in the experiment, the level of return on production assets was also influenced, to a lesser degree, by the conditions of inventories and fixed assets.

For inventories the situation was not very favorable, since only at half the VHJ's was the inventory turnover time reduced by 1 to 4 days, while in the other half, inventory turnover was by 1 to 4 days slower.

The return on fixed assets developed more favorably, for at nine of the VHJ's the indicator was better than envisioned by the plan, at two it was the same as called for by the annual plan, and at only one of the VHJ's was it worse than the plan.

An important place in the new system of plan indicators being tested in the experiment is occupied by the value added indicator, which plays an important role not only in lowering the material intensiveness of production, but also is an important motivator in the area of wage incentives.

The annual implementation plan for (labor) value added was surpassed by 10 of the VHJ's, and the other 2 fulfilled the indicator by 99 percent. Overall, the VHJ's exceeded their plan with respect to (labor) value added for 1979 by 1.7 percent, and the fact that this indicator was met to a greater extent than that for gross output (100.4 percent) indicates that this indicator is fulfilling its role in lowering the material intensiveness of production.

Exceeding the plan in return on production assets and (labor) value added and other indicators for the marketing structure, which decisively motivate the formation of the wages payable, made it possible for the majority of VHJ's in the experiment to draw wages without affecting their relation to labor productivity.

The plan for the labor productivity with respect to value added was exceeded overall by 1.8 percent, while the plan for average wages was exceeded by only 0.7 percent. In comparison with 1978 the productivity of labor rose by 6.8 percent, and average wages by 3.5 percent.

The plan for the basic component of the wage bill was fulfilled by 99.9 percent and its norm of 25.5 percent was 0.47 point lower than the plan, since it was exceeded by only 1 VHJ.

The proportion of the incentive component in the total wages payable was, in accordance with the objectives of the experiment, increased 1 point from the 1978 figure. to 19.6 percent. To be sure, the plan for the absolute limit on the incentive component of the wage bill was exceeded by nine VHJ's, but of these, five VHJ's did this while exceeding the plan for all of the qualifying indicators.

A total of 11 of the participating VHJ's adhered to the mandatory limit on their wages payable, and with the savings amounting to Kcs 208 million, they created additional resources for implementing a longer-range wage policy.

The lower plan fulfillment in the creation of material resources primarily affected the area of utilization and was reflected in the results achieved by a lower fulfillment of the plan then in 1978, both in total final sales and in general trade trends, except for exports to nonsocialist countries at wholesale prices. Just as happened in 1978, throughout the industry, in the utilization trend of industrial production, the fulfillment of tasks set by the annual implementation plan also continues to be uneven, in the sense that the plan for deliveries of machinery and equipment for investments continues to be overfulfilled (by 15.2 percent), while deliveries for the domestic trade sector are fulfilled only by 100.6 percent, those for export to socialist countries by 101.8 percent and those for export to nonsocialist countries by 100.9 percent.

For the effectiveness of export as measured by comparative indicators, better overall results in 1979 were achieved for fulfilling the plan for export to nonsocialist countries (104.4 percent) than for exports to socialist countries (99.2 percent).

Fulfilling the plan for sales and especially for deliveries for export is ever more dependent on the rapid realization of the results of research in practice in the form of innovations while simultaneously improving the overall quality of products. Consequently, special attention is devoted to these areas, which shows up in the fulfillment of the plan for the basic indicators characterizing the area of innovation which indicate that the development of innovation effort in the majority of the VHJ's participating in the experiment shows a rising trend.

The planned share of new products in the production of goods was exceeded by all VHJ's in the experiment except for the VHJ Drevarsky a Nabytkarsky Priemysel in Zilina.

The planned share of new prime quality and technologically advanced products in the volume of new products was likewise exceeded by all the VHJ's for which it was prescribed in the experiment and all of them achieved a higher share than in 1978. In comparison with the figures for all of industry in 1978 (14.1 percent) and for the first 3 quarters of 1979 (15.5 percent), 9 of the VHJ's in the experiment achieved better results for this indicator.

(15) Ratio of new products at world standard of technology to the new products by volume
(16) Plan for 1979
(17) Actual, 1979
(18) Actual, 1978

The plan for the ratio of new products at the world standard of technology in the volume of new products was prescribed for seven of the VHJ's in the experiment, all of which exceeded it. In comparison with 1978, there was a decrease in this ratio only in the VHJ Tovarny Strojirenske Techniky in Prague.

Equally promising are the results achieved in plan fulfillment and in the development of other indicators of innovation, namely the "ratio of sales collection stock replacement" and the "share of products of a high quality standard and style level in total sales, at wholesale prices." These indicators characterize the specific innovating process in the branch of the consumer goods industry; they were prescribed for the experiment's three VHJ's under the CSSR Ministry of Industry.

Further improvement was also achieved in the area of quality for that part of the production of the experimenting VHJ's that is evaluated by state testing stations.

(24) Number of the VHJ*

The volume of recognized claims, which reflect the overall level of quality, declined 13 percent from 1978.

While the overall results achieved by the experimenting VHJ's are positive in most of the areas checked, the fulfillment of the plan in individual VHJ's differed and reflected in more pronounced ways the specific conditions of the production and replacement processes.

All of the experimenting VHJ's fulfilled or surpassed their plans for selected indicators only in the areas of innovation and quality, and the newly introduced fixed-limit investment indicator, which was introduced in the experiment and which the VHJ's used primarily for modernizing their production bases. On the other hand, the largest number of VHJ's (eight) failed to fulfill their planned volume of work and deliveries for building projects budgeted at over Kcs 2 million due to insufficient construction capacity.

The best results in fulfilling the plans in 1979 were achieved by the VHJ's of the CSR Ministry of Industry. The engineering VHJ's under the Federal Ministry of Metallurgy and Heavy Engineering fell short of plans in the area of financial management, and the engineering VHJ's in the Federal Ministry of General Engineering did not attain the planned levels in exports to both socialist and nonsocialist countries. The VHJ Elitex additionally failed to fulfill export and domestic market deliveries.

2. Evaluation of the Results from the Beginning of the Experiment

The 2 years that have passed since the experiment was begun make it possible to test another element based on the cumulative evaluation of the results achieved in fulfilling the plan.

The basic tendencies in plan fulfillment by the experimenting VHJ's, which first appeared in 1978, continue essentially unchanged in the cumulative results. The aggregates also show the favorable plan fulfillment in financial indicators, cost reductions, and the differentiated fulfillment in the major sales areas. Because the cumulative monetary incentives are based, in a number of indicators, on actual results achieved not only in the implementation but in the original plan aggregates as well, the significance of the long-range nature and the stability of the plan are also improving. In this connection, it is noted that realizing the principle of long-range planning and the stability of plans in 1978 and 1979 was not without its problems, since a number of changes from the original plan were made in the implementation plans.

(12) Ratio of total costs to output less the effect of foreign trade
(13) Ratio of costs of materials and services of a material nature less fixed asset depreciation and effects of foreign trade on output
(14) Return on fixed assets
(15) Inventory turnover
(16) VHJ number[1]

Overall, the implementation plan of the VHJ's in the experiment differed in 128 instances, of which 90 represent an increase over the original 3-year plan [for the experiment], and 38 a reduction in it.

The greatest number of instances of tightening up plans resulted from the experimenting VHJ's taking advantage of the opportunity at as early a stage as the compilation of the plan, to raise the volume of their wages payable by accepting higher plan requirements for value added and return on production assets than had been set for them by the branch breakdown. Thus, the planned requirements for a return on assets were increased by nine VHJ's and for value added by eight VHJ's.

Since the system of plan indicators is an interrelated one, it necessitated modifications in the plan for other indicators, primarily the plan for costs and some areas of sales.

Reductions in implementation plans from the original 3-year plan were made most frequently in the area of sales, chiefly for export deliveries to nonsocialist countries.

3. The Results of VHJ's Participating and Not Participating in the Experiment

A comparison of the results achieved in plan fulfillment by the VHJ's participating in the experiment, and in the 1979 developments, with the results achieved by a group of VHJ's under the Federal Ministry of Metallurgy and Heavy Engineering, the Federal Ministry of General Engineering and the Ministries of Industry of the CSR and the SSR not in the experiment shows that for the most part better results were achieved by the VHJ's participating in the experiment.

The total sales plan even by economic standards was exceeded by experimenting VHJ's to a greater degree than by those not participating. Their export effectiveness, as measured by the comparative indicator, was higher for exports both to socialist and to nonsocialist countries.

The experimenting VHJ's also achieved a two-point higher plan fulfillment in return on production assets and profits than did the VHJ's not in the experiment. A cumulative comparison of the results for the 2 years of the experiment shows approximately the same tendencies.

Conclusions

The second year of the experiment in efficiency and quality management in 12 industrial VHJ's further confirmed, in the majority of cases, the beneficial effect of the new economic tools used to increase efficiency and quality and tested the effects of certain other new elements.

(18) Individuals
(19) VHJ's participating in the experiment, as a whole
(20) VHJ's not participating in the experiment, as a whole
(21) Actual
(22) Percentage of plan fulfillment

The basic trends in the management of the experimenting VHJ's which showed up as early as 1978, continued essentially unchanged in 1979. The rules of the experiment continued to exert a favorable influence primarily on the further improvements in efficiency in the area of financial management, and significantly bolstered efforts at innovation and increase in the quality of production.

The results of the experiment have not yet become clearly evident in the area of foreign relations.

The cumulative evaluation of plan fulfillment for the 2 years of the plan in essence confirms the conclusions of the annual evaluations. The improved results achieved in plan fulfillment in 1978 over 1979 bettered the cumulative plan fulfillment for the 2 years and thus created a higher basis for monetary incentives tied to the cumulative data than was the case in 1979.

On the whole, the results of the experiment in efficiency and quality management can be evaluated as positive for the second year as for the first, proof of which is that a number of its tested new elements were incorporated by the Set of Measures for Improving the System of Planned Management of the National Economy after 1980.

SLOVAK DEPUTY MINISTER DEFINES AGRICULTURAL TARGETS

Prague HOSPODARSKE NOVINY in Czech 22 Aug 80 pp 1,4

[Article by Eng Julius Medved, CSc, first deputy minister of Agriculture of the SSR]

[Text] The rise of material expenditures per unit of production and the decrease of khozraschot profitability have been clearly evident for a considerable time now, even after the completion of the restructuring of our agriculture, undoubtedly as the result of lack of progress in raising productivity and of the relatively low technical and economic standard. Compared with the world standard achieved in science and technology, the material input into intensification and replacement in our agriculture is characterized by a number of elements slowing down the improvement of the technical and economic indicators of means of production. Elements or systems of a revolutionary nature which could mean the introduction of innovations of a higher order in biology, chemicalization, methodology and technology appear only exceptionally and, most importantly, the coordination of these mutually connected elements of scientific and technical progress, which is indispensable given the specific biological-technical nature of agricultural production, manifests serious shortcomings.

Practically only our cereal production, specifically the densely sown cereal cultures, have reached a standard comparable to that of countries with developed intensive agriculture. Our research and improvement stations have already produced wheat seedstock yielding 8 to 9 tons per hectare, and barley yielding 6 to 7 tons per hectare, and seedstock improved in other countries is also available to us. Overall, fertilization, weed control and also mechanization of our cereal cultures exhibit a high standard.

Also results of the hybridization program in pig raising which yielded breeds with potential weight gains of between 600 and 650 grams per day in animals raised for slaughter, and which exhibit a higher proportion of meat and good feed conversion, approach the standard of highly developed agricultural countries. Also the results achieved in poultry raising are comparable with the world standard. But in both these animal productions sectors nutrition, raising techniques and technological production systems are not equal to the biological potential of the animals.

The Call for New Criteria

Certain advanced elements of scientific and technical progress which must be evaluated in terms of the current world standard could be introduced also in the exploitation of the bioenergetic soil potential, feedstuffs, oil-bearing crops and a number of other crops, and in cattle and sheep raising. But all these sectors or production branches are characterized by lack of comprehensiveness of scientific and technical progress, and a lack of balance of biological, technical and technological elements over the entire production cycle. The process of industrialization in our agriculture and its material tools exhibit many elements characterizing extensive agriculture and low quality, while also the intensification and productivity-raising means, such as chemical fertilizers, mechanical means for technological field operations, animal husbandry, transportation and manipulation of bulk supplies and building materials are being produced (with a few exceptions) at high cost and with high material and power input. Frequently in agriculture the use of these means does not result in a commensurate saving of human labor. A contributory factor in the overall low technical and economic standard of means of production in this sector is also, for either technical or economic reasons, the inability of using rationally a number of machines and means of transport, and technological installations and materials under difficult natural conditions.

Such a critical assessment of the technical and economic standard of our agriculture is justified mainly because existing and prospective conditions governing overall economic growth in our country place qualitatively more exacting requirements on agriculture, the direction and ways of its development and its support base, which calls for the application of new criteria in assessing achievements and the setting of new objectives and tasks. We must respect more than we have until now the harsh reality that limiting factors such as the immutable acreage of the land area are being further complicated by the fuel and energy shortage, water supply and pollution problems which also affect agriculture, the problem of industrial emissions, the supply of raw materials and technological equipment for fertilizer production and the production of pesticides. In addition, chemicalization of agricultural production and large-scale animal production methods render protection of the environment more difficult and aggravate the shortage of labor.

Under these increasingly difficult conditions augmenting the degree of self-sufficiency in foodstuffs and some other agricultural crops used in industry is possible primarily only by intensifying and accelerating the implementation of scientific and technical progress.

Sometimes the question is being asked whether in fostering self-sufficiency priority should be given to the resulting intensification of agricultural production or to the greatest possible reduction in expenditures per unit of production which is usually stressed in connection with the endeavor to raise the economic efficiency of agricultural production. Naturally,

intensification of production, albeit differentiated according to soil, climate and overall production conditions prevailing in individual oblasts and enterprises, is the only available alternative.

Therefore, the rational answer in getting at the root of the above problem should not be continued intensification of production by increasing chemicalization, mechanization, etc. to raise soil fertility, but finding ways of reducing the material, power and labor requirements while maintaining the socially necessary production structure and intensity. From this it follows that in agriculture as well, the term objectively progressive in the economic sense is not just an scientific and technical means which will increase output and labor productivity, but also those means likely to save materials, power and labor. In this connection it is worth mentioning that the cost of many material elements of scientific and technical progress, especially of mechanical equipment and construction materials, is not commensurate with the production gain achieved, but that also in this way agricultural production can also only be rendered costlier.

Plant Production

A priority task in research, but also in the field of application of proven scientific findings, is mastering the problems connected with increasing crop production by raising soil productivity as the basic condition of all agricultural food production and of raw materials for many branches of the consumer goods industry.

Abiding by the necessary water supply regime and the correct supply of nutrients primarily by increasing the doses of chemical and natural fertilizers, choosing crop-growing localities with optimal production conditions, and applying scientifically proven planting procedures to exploit individual soils and ecological conditions to best effect, occupies a key position in this area. Calculations based on research and the results achieved by advanced methods applied in practice reveal that irrigation raises crop yields by 25 to 30 percent, and soil drainage by 15 to 20 percent on the average. Therefore, the SSR long-term improvement program includes a vast construction program of irrigation and soil drainage installations. In the coming 5 years the guidelines for the Seventh Five-Year Plan call for the preparation of a program to extend the area of land under irrigation by 120,000 hectares by 1985, and draining a land area 90,000 hectares in size.

Today, primarily the rational use of chemical fertilizers is in the forefront of efforts to raise soil fertility. Results acquired both in research and practice reveal that chemical ferilizers applied on the basis of exact analytical determination of supplemental requirements of crops can raise the production increase due to fertilizer application by 15 to 20 percent over localities where this practice is not followed. One of the most important tasks in the activity of agrochemical enterprises in applying scientific and technical findings in the use of chemical fertilizers, and progressively also of manure, is to exploit as soon as possible this large reserve production potential in accord with the resolutions of the 13th CPCZ Central Committee Plenum.

Also worthy of consideration is the finding that productivity of our land can be increased by approximately 25 percent by intensive exploitation of the bioenergetic potential of the soil by maximum improvement of its organic component through fertilization and the choice of crop production structure and crop rotation practices which most benefit the upkeep and fostering of soil fertility. Of course, raising soil fertility by cultivating the most suitable crops and application of the right methods conflicts in practice with other important considerations which have to do with the geographical distribution and structure of crop production.

Several crops are so important that they must be grown regardless of their "fertilizing effect," frequently also under less suitable soil and weather conditions. In the case of other crops the important factor which must be considered in deciding on their geographical location is the distance from the processing industry, the market etc. But ample opportunity exists for the application of scientific and technical findings to intensify and increase crop production efficiency.

At the same time increasing soil fertility is one of the key conditions in taking advantage of the results of strain and seedstock improvement work. In this field the 13th Central Committee Plenum has placed emphasis primarily on reducing the time needed to improve biological material and accelerate the introduction of new proven crop strains and hybrids into general use for which we possess objectively more favorable conditions than capitalist countries with predominantly small farms.

In connection with this task our seed improvement stations aim at achieving in 1985 a cereal production potential exhibiting indicators comparable with the world standard, specifically with wheat seedstock yielding 9 to 10 tons per hectare, barley yielding 7 to 8 tons per hectare, corn yielding 10 to 20 tons per hectare and legumes yielding 5 to 6 tons per hectare which, even if met only by 60 to 70 percent of potential under production conditions promises to result in a dynamic increase of cereal production. In this effort greater emphasis must be placed also on improvement and productions, as well as on the qualitative characteristics of the grains, which goal is also being pursued by license procurement of biological material.

In the case of sugar beet the use of high quality seedstock is vital for economic reasons which can be achieved mainly by seed improvement work, propagating our own seedstock under optimal conditions of climate in other countries such as the Socialist Federal Republic of Yugoslavia. The objective to be attained in strain improvement work is to increase the sugar content of beet by 18 to 20 percent and reach a standard in the agrotechnical cultivation system and in harvesting which will yield 6 tons of refined sugar from a hectare of sugar beet, or roughly 20 percent more than the yield which our best sugar beet growers are able to achieve today. This would at the same time enhance the profitability of the sugar beet industry by better utilization of capacity and the reduction of processing expenditures.

Overall soil and ecological conditions in the SSR are most suitable for intensive raising of potatoes. But achieving self-sufficiency in potatoes is one of the specific political and economic objectives. The task assigned to plant research and improvement facilities calls for developing potato strains yielding 3.5 to 4.5 tons per hectare, increasing their resistance to extreme weather conditions and diseases, raising the starch content of industrial potatoes to approximately 20 percent, or by about 25 percent above the current content and raising the quality of eating potatoes.

With respect to bulk feeds research workers are expected to develop biological material with higher protein content and stabilize the yields of feed crops at 12 to 14 tons of dry matter per hectare, in the case of grasses at 7 to 8 tons of dry matter per hectare. Scientific and technical research work aimed at finding a comprehensive solution to harvesting, improving the storage life of bulk feeds and finding new preservation methods should yield feed quality guaranteeing a 7 to 8 liter milk yield per basic feed ration, a yield exhibited today only in our best agricultural enterprises.

In horticulture, in view of the necessity to increase not only the consumption of fruits growing in the mild climatic zone but also to achieve a measure of self-sufficiency, improvement work aims at developing high yield strains with high frost and disease resistance. Much has been lost by the failure to conduct adequate high quality studies of ecological conditions suitable for the establishment of large-scale fruit orchards, an objective which is now being pursued with increased emphasis.

In view of the biological nature of agricultural products, scientific and technical research aiming at prolonging the storage life of products is especially important. In this respect very encouraging results were achieved for example in the USSR by the application of the so-called electroionization technology in the storage of some agricultural products like fruits, vegetables, potatoes and other crops which exposes them to the action of ozone. This practice extends storage life, saves energy which would otherwise be required for cooling and decreases quality and quantity losses during storage and long-distance transportation.

The outlook is very promising for the development and practical application of growth stimulants which make it possible to influence specific developmental physiological processes of plants. The preparations are being produced by microbiological methods or by chemical synthesis. Such preparations stimulate the ripening process, raise harvest yields and improve the quality for example of cereals, fruits and vegetables, sugar beet, grapes and other crops on condition that they receive a balanced supply of nutrients during growth.

Animal Production

Our country now expects to take advantage of the world genetic fund also in cattle improvement work to achieve greater differentiation between breeds and crossbreeds raised for milk production of slaughter. The objective

is to improve the productivity of the biological material, to achieve a milk yield of 6,000 to 7,000 liters per cow, in cattle for daily weight gain of 1,200 to 1,300 grams per animal, and in breeders a yield of 110 calves per 100 cows, all indicators which are considerably higher than those achieved by our best cattle raisers today. The prerequisite for the exploitation of such high biological potential is the availability of feed of high quality, and adequate quantity in physical, chemical and biological form guaranteeing balanced nutrition of the animals. A number of other factors, mainly of technical, technological and organizational nature, influence large-scale cattle raising where international cooperation is likewise necessary.

The lack of a comprehensive approach to the solution of these problems in practice, the inability to control the effects caused by interaction of the biological material, feed, raising methods and technology are among the reasons why most of our large-scale cow barns lag far behind their expected yields and profitability.

The problem of reconciling biological, nutritional and technological requirements in intensive and economically efficient production exists also in large-scale sheep raising enterprises and some poultry raising enterprises. Essentially this is a result of a lack of mastery of industrial production technology.

Considerable gaps and bottlenecks exist in technical and technological systems in both crop and animal production, especially in the lack of comprehensive handling ability and efficiency of mechanical means of complete technical and technological lines. Smooth functioning of technical operations in the entire production process is especially important in raising the intensity and economic efficiency of agricultural production and attaining a desirable quality of products. Of special importance, moreover, is the time factor, the need to carry out these operations within agrotechnically optimal time periods, maintaining optimal intervals between feedings, milkings, etc. Therefore, in this area efficiency and reliability are prime criteria of scientific and technical progress and the quality of mechanization in agriculture.

Much room still exists in agricultural production for mechanizing operations carried out now by manual labor, automating stationary and some mobile processes, especially in animal production but also in crop production. Great reserves in utilizing mechanical means to better effect exist in replacing tractors with automobiles as a generally more rational means of transportation, which according to documents from the 13th CPC Central Committee Plenum would yield great savings in fuel and labor. Mechanized means must be used much more rationally in agriculture, machinery must be considerably better cared for and a higher standard and better division of labor must be achieved in repair shops.

Scientific and technical progress penetrates into agriculture also by way of such components of the material and technical base as are facilities for

raising animals, the processing of harvest crops and their storage, the storage of fertilizers, etc. In this regard the 13th CPC Central Committee Plenum again emphasized the necessity of following consistently a construction policy aimed at technically advanced, but at the same time economically advantageous, solutions by reducing material costs, increasing the use of prefabricated parts, utilizing a single design repeatedly, and reducing capital expenditures per unit of capacity. These criteria are also being applied in evaluating some construction projects which are to be built as part of the plan for the development of science and technology. But it appears that while there is no lack of initiative in practice, there is unfortunately also more dissension. The problem of rational utilization of manure from large-scale animal-raising enterprises to eliminate its negative effect on the environment has not yet been resolved satisfactorily. Therefore, improvement aiming at raising the technical and economic standard of agricultural capital construction are being specified which are designed to achieve marked improvement in the course of the Seventh Five-Year Plan.

Economic Stimulation

One of the problems is to raise the interest of the suppliers of seeds and seedstock, chemical fertilizers, agrochemical services, machines and technical installations, repair services and designers and builders of agricultural facilities in the final results and technical indicators to achieve a high standard of agricultural production. Here serious deficiencies still exist. Therefore, proposals dealing also with this serious problem are being considered in connection with measures designed to improve the system of planned management in agriculture.

No less important is to offer materially more attractive incentives to users of advanced technologies, and to keep alive their interest in using also other than material incentives to raise the technical and economic standard of agricultural production. In accordance with resolutions of the 13th CPC Central Committee Plenum, beginning with 1 January 1980 several economic measures have already been implemented which are designed to shore up not only the khozraschot situation of JZD's and SM's [state farms] in all conditions of production, but also to raise the quality of products and exert pressure for better utilization of chemical fertilizers, feeds and economy in the use of labor.

Our scientific and research potential must be further strengthened, especially its quality. The scope of professional training of research workers must be broadened, especially in the field of genetics, physiology, biochemistry and microbiology. Larger and more comprehensive research and development facilities must be gradually established where advanced scientific research laboratories and equipment can be put to rational use.

Research, Practice

Great potential reserves for increasing the efficiency of scientific and research efforts, and applying scientific findings in practice exist in

closer cooperation of agricultural research with research and development work places of other economic branches manufacturing means of production needed in agriculture where new technical findings can be practically applied. This is so especially in the field of agricultural engineering, agrochemistry, the pharmaceutical industry, the building materials industry, etc. This calls for further consolidation of the function of a unified plan of scientific and technical development, the coordinated development and utilization of international scientific and technical cooperation also in these branches, more frequent use of international probelm-solving teams, increased purchase of production licenses, etc. It is especially important to insure that expenditures designed to intensify industrial production are economically justifiable.

The call for faster introduction of findings of applied research in practice is justified. To that end agricultural research, including its technical, developmental and application components, must be further expanded and built up as has already happened organizationally for example in the seed improvement and production sector.

The principal role in transforming findings of scientific and technical research into usable production tools (seeds, animal breeds, feed mixes, machinery, fertilizers, etc.) must be assumed by scientific research, developmental and production organizations. By the implementation of scientific and technical findings of a nonmaterial nature and the integration of elements aimed at implementation into comprehensive management systems the role of our transfer organization--the Institute for Scientific Systems Management and its territorial netwoork of branches--will be further strengthened.

The knowledge and experience gained in implementing scientific and technical findings in our agriculture demonstrate that great delays still exist in developing and producing tested and proven research results, and that little of what is available is also being widely used in practice. This phenomenon must be countered more effectively by a comprehensive approach and coordinated procedure by economic management organs by integrating the efforts and means of scientific, research, developmental, design and production organizations, especially when they are part of different ministries.

The efficiency of work of these organizations, collectives and individuals should also be evaluated and assessed on the basis of stricter criteria. In user organizations good results are usually achieved where management workers are in the forefront of the struggle for the implementation of scientific and technical findings in practice, where the application of new findings and experiences is carried out flexibly and where the organizational effort for carrying projects to fruition does not weaken even when difficulties arise.

BRIEFS

ROSTOCK PORT EXPANSION--The Johnson Concern has signed a contract for a 500 million deal with the German Democratic Republic. Svenska Vag Inc will continue the expansion of the port at Rostock. This is half the order, approximately 250 million kronor. In return, A. Johnson and Company will purchase industrial goods from the German Democratic Republic for approximately 250 million kronor. The contract was signed last Wednesday in Leipzig. The deal means that the international division of Svenska Vag, the Johnson Construction Company, will be continuing the expansion of the port at Rostock. This time, the expansion concerns a general cargo harbor with three quay berths, storage building, crane lines, land work, etc. The concern last year got its first order, to the value of 360 million kronor, which involves the construction of a grain harbor. That project will be completed in the fall of 1982. The construction of the general cargo harbor will be started immediately and is scheduled to be completed by the end of 1983. The project will provide employment for 30 Swedish staff members and 125 construction workers at the site. The contract was concluded between, on the one side, Svenska Vag Inc --through the Johnson Construction Company--and the trading company A. Johnson & Co , and, on the other side, the foreign trade organization of the German Democratic Republic, Industrie Anlagen Import. A. Johnson & Co HAB recently opened an office in Berlin. ECONOMIC RELATIONS WITH DEVELOPING COUNTRIES DESCRIBED

Budapest NEPSZABADSAG in Hungarian 13 Aug 80 p 10

[Article by Janos Tormasi, main deputy chief, Ministry of Foreign Trade: "Our Economic Relations with Developing Countries"]

[Text] Extreme viewpoints about the importance of the economic relations we are maintaining with developing countries, and in the evaluation of the hidden potentialities in developing these relations, are not unusual. Overestimation of the importance of the relations and of their outlook for further development, as well as intolerable disparagement of the cooperation, can be found also.

The share of developing countries in total Hungarian exports in recent years has been somewhat over 8 percent, on the average. Of nonruble accounting exports, however, (including nonruble accounting exports to socialist countries) nearly 17 percent was directed to developing countries. The volume of our exports to several developing countries is competitive with that of our exports to important capitalist markets. For example, in 1979, Iraq was in fifth place among out nonsocialist exports, surpassing Great Britain, France and the United States, among others. In 1979 Kuwait, Syria, Algeria and Libya purchased as much Hungarian export merchandise as did Greece, Belgium or Finland, for example. Lebanon, Iran, Nigeria, Tunisia, India and Brazil are no less important buying markets.

The proportion of our imports from developing countries is somewhat less than our exports. It comprises nearly 6 percent of our total, and nearly 11 percent of our nonruble account imports. According to 1979 data, among our more significant suppliers, Brazil was in sixth position among nonsocialist countries, surpassing, for example, France and Holland. We purchased more from Iraq than, for example, from the United States or Sweden.

The developing countries' share in the exports of several product groups and in the imports of certain rather important merchandise surpasses the previously mentioned proportions considerably. For example, nearly 40 percent of our machinery exports for nonruble accounts is to developing

countries, and 55 percent of our nonsocialist imports of agricultural and food industry products originate from these.

Last Year's Results

We consider the 1979 results as favorable from the standpoint of our economic relations. The value of our exports to developing countries exceeded $700 million, which is 26 percent higher than the year before. Our imports amounted to $655 million, which exceeded the previous year's amount by 4 percent.

The composition of the trade also turned out to be favorable. Machinery, assembled equipment, vehicles, instruments and components comprised 35 percent of our exports, while another 21 percent consisted of bulk metal items and industrial consumer goods. The proportion of metallurgical and chemical industry materials comprised nearly 21 percent. The remaining 23 percent was composed of shipments of food industry products, live animals and other agricultural products.

The major portion of our imports consists of energy sources, raw materials and agricultural products which may be acquired economically from developing countries. More than 10 percent of our purchases consist of industry products, industrial consumer goods, tools, bulk metal items and, to a lesser extent, machinery. The proportion of food industry, semifinished and finished products exceeded 30 percent.

Last year more than 800 Hungarian specialist worked in developing countries, assisting the development of the national economies of the host countries. This is important from the standpoint of developing our economic relations. Nearly 60 citizens of developing countries received specialized training in Hungary.

The dynamic growth of trade continued during the first half of 1980. Our exports are expected to reach $850 million, and our imports to approach $707 million.

Tasks of Development

The intent of the policy to develop the economic relations which we are maintaining with developing countries was set down by the twelfth congress of the Hungarian Socialist Workers Party as follows: "We are further strengthening the mutually advantageous economic relations with developing countries. Within the realm of our capabilities, we are aiding them in consolidating their economic independence. Foreign trade with developing countries is to increase at a rate greater than the average."

The tasks are complex. We must continue to dynamically develop the value of exports to developing countries. The merchandise structure of exports is to be made more modern and more profitable. Thus, our attention must be concentrated primarily on two branches of our exports.

The exports of machinery, complete installations, vehicles, instruments and generally competitive and profitably marketable products manufactured with modern technology and specialized skill are to be increased. In harmony with the planned development directions of the Hungarian machinery industry and the growing needs of the developing countries, our exports must place greater stress on the deliveries of various production and service systems (agricultural, educational, public health, water and transportation).

In addition, in our many important buyer's outlets (Iraq, Kuwait, Libya, Saudi Arabia, Iran, and Nigeria) and many other developing countries, we have not nearly exploited the full possibilities of expanding our agricultural and food industry product exports. The most important condition for so doing is the expansion of our exportable merchandise bases. There are significant needs especially for cattle and beef, frozen chicken, sheep and lamb, as well as for goats and edible oils.

Through Improving Market Efforts

In order to implement the planned dynamic development of our exports, more careful work appropriate to the rapidly increasing demands must be performed as much in trade, narrowly defined, as in production. We must improve our exploration of market requirements and must adapt better to the customs and peculiarities of developing countries. Our enterprises must significantly improve their performance in order to exactly satisfy their contractual obligations, especially in respect to quality and delivery schedule. Through failures here, the enterprises will be forced to learn, through not only large direct losses, but rather through the loss of possible future business, that the developing nations market is also becoming more and more exacting.

We must explore more thoroughly and better exploit the most favorable export potentialities to the developing nations. It may be possible to replace other unfavorable foreign import sources with the supply available from developing countries. Energy sources and certain raw materials (unrefined phosphates, iron ore, raw rubber, wool, cowhide, etc) will continue to comprise the largest factors in our imports in the future. In concert with the development of the delivery capabilities and the growing requirements of the developing countries, however, the imports of processing industry products (primarily textile and leather industry merchandise, tools, bulk metal and simpler machinery) will also increase. At the same time, it also appears that, because of gradual saturation of our domestic needs, our imports of several tropical products (coffee, cocoa) will grow at a slower rate.

Long-Term Cooperation

We must place great stress on broadening longer term cooperative relations with enterprises of developing countries. The expansion or even the

maintenance of our market position over the long range is unthinkable merely on the basis of traditional export-import traffic. Above all, in the cooperative manufacturing of certain transportation vehicles, in the agricultural machinery manufacturing industry and in the area of agricultural production, possibilities for further implementation of cooperation are apparent.

Often the successful implementation of production cooperations requires that Hungarian enterprises participate in joint economic undertakings in developing countries and establish either their own or joint ownership enterprises. There have been a number of such initiatives thus far, but the development is slower than is desirable. Naturally, we must continue to exercise caution so that the burden and risk of such undertakings remain within our means and within the framework of economic sense. A good many impeding factors (for example, the relatively large investment necessary for just such undertakings; perhaps unfavorable local circumstances or requirements, etc) should not be disregarded. However, considerably more dynamic development of this form of cooperation is necessary to expand our economic relations.

IMPROVEMENT, SHORTCOMINGS IN TRADE BALANCE VIEWED

Budapest NEPSZABADSAG in Hungarian 24 Aug 80 p 3

[Article by Istvan Foldes: "What Is Welcome and What Is Not"]

[Text] The data of the first half year attest to the welcome improvement of the country's foreign trade balance. The import surplus of the first 6 months is exactly one-half of the previous year's. This is due as much to the nearly 4.5 percent decrease in imports as to the 3.8 percent increase in exports. The balance improved especially in the nonruble trade account. In this relation, the imports decreased by 7.1 percent, compared to last year, and exports surpassed last year's amount by 13.2 percent. As a result of this, the passive balance of the nonruble trade account dropped by an even greater amount than planned, to one-fifth of what it was.

The Chief Goal Is Realized

It is common knowledge that, appropriate to the direction chosen by the 1978 December resolution of the Central Committee, this year's national economy plan selected as its chief goal the improvement of the national economy's balance status, and primarily the improvement of the nonruble account foreign trade balance. The rate and proportion of production and domestic consumption are to be subordinated to this goal. The accomplishments of the first half year indicate the successful implementation of this economic policy. They are proof that the party's economic policy goal was realistic, and that economic direction utilized fundamentally appropriate methods to accomplish this goal.

Economic planners realized that the rectification of the foreign trade balance could be accomplished only through a temporary slowing of production, and to a greater extent, through a reduction in domestic consumption. Appropriately, the increase in the national income slowed somewhat even last year, and investment activity and the population's real income stayed at the 1978 levels. This year's plan was also expecting a relatively small increase in production--although exceeding that of the previous year somewhat--and a decrease in domestic consumption.

The production data of the first half of this year indicate that while the balance improvement is more favorable than planned, the growth rate continued to decrease. However, while last year the national income's failure to reach the planned level was basically caused by the stagnation of agricultural production due to unfavorable weather, the industrial production decrease in the first half of this year is caused by falling behind schedule. The gross production of socialist industry was 1.8 percent less in the first 6 months of this year than in the first half of 1979. Within this, the performances of the electrical energy industry and the building materials industry exceeded those of the previous year, food industry stayed even, but the other industry branches produced less than in the first half of 1979. The building industry's production decrease was greater than planned. Thus, The improvement, exceeding the plan, in the balance situation is in no small measure the result of the lesser import needs of a declining industrial production.

The industrial production decrease is not large scale, and the fact that it happened coincidentally with the realization of our other objectives (since the foreign trade balance improved, and the stockpiles decreased, rather than increasing even contains a certain positive element within itself. Nevertheless, it still indicates--and this is primarilly what is not welcome--that our industry's adaptation to the altered conditions is still slower than is desirable.

The lower domestic demand had to induce enterprises to endeavor to put their released capacities to use primarily in export-directed production, that is, to replace imports, The half year's data reflect that endeavors to improve the structure of industrial production undoubtedly increased. This was definitely revealed by the dynamic growth of exports. However, it was not enough to compensate for the decrease in solvent domestic requirements. If this development in industrial production--although it did improve the foreign trade balance, and in our situation today this is primary--were to become permanent, it would cause a standstill in our total development. This is not desirable at all.

Too Much Caution

The change in the regulation system, and especially the enterprise uncertainty caused by the new price system, undoubtedly had a role in the development of industrial production in the first half year. Because of late publication of production prices and the production price halt in the first quarter, many enterprises postponed the finalization of contracts. Caution was especially noticeable in enterprise investments. It is understandable that enterprises needed to survey their probably income situations and to formulate appropriate strategies. However, passivity is still discernable in places, although it became apparent that the income situation of most enterprises under the new price system is more favorable than they expected. There are some enterprises, however, which are struggling with either temporary or prolonged difficulties. The resolution of the situations of several of these is requiring central intervention.

In any case, that there are very divergent performances hidden behind the industrial or branch averages may be considered a favorable sign. In the machine industry, for example, in the first 6 months the Automobile Electric Equipment Factory and the Hungarian Ship and Crane Works produced 20 and 5 percent more respectively, while the Communications Technology Enterprise and the Office Machine and Refined Technology Enterprise produced 16 and 23 percent less respectively than during the same period last year. In the cotton industry, during the same period, Rabatext produced 5.3 percent more, while the Kobanya Textile Works produced 10 percent less. Shoe industry production increased by 2 percent, but within this, the production of the Szabolcs Shoe Factory increased by 30 percent, while that of the Duna Shoe Factory decreased by 2 percent. The furniture industry produced 1 percent more, but, for example, the production of the Cardo Furniture Factory was 12 percent greater, and that of the Bacska Furniture Industry Enterprise was 15 percent less than a year earlier.

We are not to be misunderstood as saying that enterprises are to be evaluated solely on the basis of the dynamism of gross production, since, for example, production decrease can be a temprorary phenomenon due to structure changes, and large scale production increases can also be the result of seasonal boom factors. The differentiation, however, is definitely a good sign of the beginning of realignment and is thus welcomed.

More Rapid Changes in Structure

The improvement of the production structure, to which the 1977 October resolution of the Central Committee referred with special emphasis, is naturally a multiyear--actually a continuous--task. Today it is quite apparent that the noticeable results of government and enterprise measures directed toward this end appear only years later. Even such relatively rapid and successful actions as investments supported by bank export development credits are mostly producing their significant export merchandise bases only after 2 or 3 years. (In any case, last year an income of $870 million was realized from the production of the investments implemented within the framework of this credit construction.)

Nevertheless, the past months of this year call attention to the fact that enterprise activities directed toward alteration of the structure are not nearly sufficient. This is so all the more because the possibilities for external balance improvement through reductions in domestic consumption have, for the most part, been exhausted. Thus the basic problem of economic development has become: how capable are enterprises in modernizing their production, in improving efficiency and in reducing their manufacturing costs.

It remains invariably true that the country does not prosper from production quantity, but rather that production's income generation is primary. We shall continue not to make a fetish of gross production quantity or of its growth rate. The national economy plans, however, are expecting that the temporary necessary growth rate decrease be accompanied by the reorganization of the production structure, by the facilitation of a more rapid development

of production and national income, and, along with it, by an increase in domestic consumption and the more rapid creation of the conditions of economic and social progress. Within this concept, of course, temporary growth stagnation may perhaps be desirable. It can only be permitted, however, if very active, efficiency-increasing, production structure-improving, cost-reducing, balance-improving effort is inherent in it.

Soon three-quarters of the year will be behind us. The part that has passed, or rather, the data which is available from it indicate that the fundamental endeavor of our economic policy is being realized--the external equilibrium of our national economy is turning out to be even more favorable than expected. As far as industrial production is concerned--this is the only thing discussed in some detail in our article--indications are that a recovery can be expected during the second half of the year, and that on the annual level, industrial production will equal or perhaps slightly exceed last year's level.

On the Eve of the New Five-Year Plan

Even greater activity and more initiative are needed for the proper preparation for the coming five-year plan and even more for the subsequent plans. Above all, the nearly 2-year long improvement trend of the national economy balance must be strengthened. The improvement in industrial performance and agricultural production which are expected to be appropriate to the plan can provide the opportunity for us to bring the country's foreign trade balance into equilibrium sooner than expected. While undoubtedly the development of the capitalist economy is not making the work of our businessmen easy--to say the least--the good experiences of the first half year indicate that it is possible to sell at a favorable price even under unfavorable market conditions, as long as the quality and technical characteristics of the products satisfy the purchaser's requirements, and if those active in foreign trade felixibly exploit the opportunities presented by the market.

With the end of 1980 not only the year is being concluded, but also a five-year plan period. Thus, in the remaining months we must work not only to improve the year's performance, but also to lay the foundations and make proper the preparation for the next 5 years. The party's 12th congress outlined the chief features of the next plan period, and the enterprises are continually receiving more information to carefully prepare their plans from the National Planning Office and the ministries. There is a need for planning and recommendations reflecting a sensible enterprising spirit--thinking and recommendations with which it is possible to genuinely alter and solidify our economy, make our work more effective and create the conditions for improving living conditions and the standard of living.

This is the ultimate goal. We view the stagnation of the standard of living as an unavoidable period in our economy, a period which we would like to have behind us as soon as possible. We know that this depends neither on our determination, but that world market factors also have an effect on when we may have our difficulties behind us. However, our conscience will only be clear if we do all that we can to more rapidly improve the production structure and to improve its effectiveness.

DEPUTY MINISTER INTERVIEWED ON FUTURE OF MINING INDUSTRY

Budapest MAGYAR HIRLAP in Hungarian 7 Sep 80 p 5

[Interview with Dr Laszlo Kapolyi, deputy minister of the heavy industries, by Ferenc Vicsek: "Mining Is Competitive"]

[Text] Dr Laszlo Kapolyi was born in Ujpest in 1932. Between 1950 and 1962 he earned PhD's in general engineering, mining engineering, then in industrial economics. After 1951 he worked in planning institutions. From 1953 to 1976 he worked at the Tatabanya Coal Mines, first in the production departments, later in various management assignments, and finally as chief development engineer. He has been deputy minister of heavy industry since 1976. In 1968 he became candidate of technical sciences, and received his PhD of technical sciences in 1975. Since 1978 he has been honorary university professor of the Eotvos Lorand University of Sciences [ELTE]. In 1979 the Hungarian Academy of Sciences [MTA] elected him to corresponding [associate] membership.

Mining's growth cannot be studied solely on the basis of the general increase in the value of raw materials. This branch of industry, with its definitely high demand for investments, is unable to follow directly the strong fluctuations in the system of values. That is, changes in the economic status of mineral raw materials can be followed from one day to the next only at the cost of great scarifices. However, falling far behind the global value changes also requires similarly great sacrifices. Expansion in opening up the natural resources depends to an especially large extent on the national economy's production structure and on its expected changes. Therefore, each and every idea for the expansion of mining also competes with the modernization programs of the other industrial branches, while at the same time it is also closely interrelated with those.

Therefore the outlook for mining--which is, after all, a promising one--can be described only by taking these viewpoints into consideration. Our reporter Ferenc Vicsek talked with Dr Laszlo Kapolyi, deputy minister of heavy industry, about this.

[Question] Generally the development of mining derives from the growth of the economy. However, this might even lead to the conclusion that the miners can count on only a modest rate of expansion in the near future, since in the final analysis the projected very moderate growth in demand and the energy sources under construction do not justify vigorous development in opening up mineral raw material resources. Is this true?

[Answer] To answer this, the situation of mining's individual branches have to be separately examined. On the one hand, full or partial fulfillment of the increased demands is not the only task the development of mining has. In some cases it also has to substitute for or replace imports; and on the other hand the general goal is to achieve as high a degree of processing of the mineral raw materials as possible, and to use them comprehensively in as broad an area as possible.

To start with the energy sources of special significance, it can be concluded that our basic opportunities for satisfying the demand are: increased domestic coal production, further exploitation of the domestic petroleum and natural gas resources, nuclear technology also based on the domestic production of uranium ore, and the import of energy sources. However, the possibilities of combinative economic manipulation with them are narrowed down by the fact that our hydrocarbon resources are limited. Over the long range we can expect to maintain the present production levels only if our geological research is successful, and if the mining technologies are modernized. The perspectives of uranium mining are unquestionally in order. In the final analysis, we have mineral resources offering significant production expansion only in coal types. The known and expected resources make twice today's production level possible until the end of the 21st century. Why is this a decisive fact? Because, due to the given circumstances of the mineral resources, decreasing the import of energy sources can be counterbalanced only by increasing domestic coal production, as a realistic alternative. And in energetics the resources and users form an interrelated system, which cannot be left out of consideration in reshaping the structure of the country's energetics system. And, in addition to the commonly known changes in the system of values, reshaping the energy structure is justified also by the fact that the imported hydrocarbons can be used to greater advantage in the chemical industry, in petrochemistry--and the natural gas in metallurgy and in use by public entities--than in generating energy. Thus it is not expeditious to maintain the present energy production structure in which each year we burn several million tons of petroleum and several billion cubic meters of natural gas in power plants.

The means of modernizing energy production are: decreasing the growth rates of demand and of specific consumption, increasing the degree of processing hydrocarbons, construction of nuclear power plants, and increasing coal mining, all taken together. By decreasing the use of hydrocarbons in energetics their use in the chemical industry can be increased, because this serves the production of new and more valuable products to a greater extent than in the present. Thus, coal will take over the role of hydrocarbons removed in this manner from the energy policy. In the next 30 to 40 years, coal and the nuclear power plants can together, in a 50-50 split, cover the increasing demand for electrical energy.

[Question] What will be the extent of change this will mean in the country's energy structure between now and the end of the century?

[Answer] According to our studies, 3 to 4 million tons of petroleum or petroleum-equivalent natural gas can be replaced by coal per year: this much petroleum can be used for products processed on higher levels. However, in order to do this it will be necessary also, in the coal-based energetics--which has again earned its right to existence--to use such higher technological standards that there will be no mean "retrogression" in comparison with the use of hydrocarbons. By means of the combinative energy policy we can thus succeed by the end of the century--by modernizing the production structure--in satisfying 50 to 60 percent of the expected energy needs with domestic resources.

[Question] What role will our other mineral resources play in this combinative raw material policy?

[Answer] Here we must talk about two significant domestic mineral resources: bauxite and copper. Processing industries can be economically built on both, so that production is not being forced to import raw materials. The bauxite-alumina-aluminum industrial branch has successfully accomplished the development ideas. We have achieved such high production and processing standards based on the quantity and quality of the bauxite finds, and we have developed such a production structure--more precisely, we have the possibilities to further develop the production structure in such a way--as to offer exportable products in every phase of production. That is, all expenses of production are recovered in aluminum's world market price, and the world market is glad to receive this characteristically energy-demanding product. In the meanwhile, the development of production built on aluminum has become an integral part of the Hungarian industry's structure, and has become one of its outstandingly well developed branches. We have resolved most of the smelting within the framework of the Hungarian-Soviet aluminum agreement, based on mutual advantages. However, in addition to maintaining this, we have also prepared to increase several-fold the capacity of our own aluminum smelting, the basis of which is a possible approximately 20 to 30 percent increase in bauxite mining production.

Speaking of the perspectives of mining, we must also mention the copper ore find at Recsk. In addition to copper this also contains lead, zinc and valuable rare metals. Thus, a vertical processing industrial complex may come into existence based on copper ore mining which, when coupled with the production development in Csepel, may also create the merchandise basis for significant exports, in addition to fulfilling the domestic needs. And the lead and zinc obtained from the cooper ore will increase the domestic supply of nonferrous metals, primarily to replace some imports. In addition to all these, the mining of a number of nonmetallic minerals (pearlite, zeolite, dolomite, etc.) can also be competitively developed.

[Question] In the final analysis, such broad reliance on the domestic resources means industrial development which produces raw materials. Due to its high demand for investment, the expansion of mining ties down a signficant share

of the national economy's development resources. Thus, of these resources already in short supply, even less will be available for modernizing the processing industries; that is, this will conserve its production levels and structure.

[Answer] The profitable extent of increasing the production of domestic mineral raw materials is necessary precisely because of the national economy's modest development opportunities. In the final analysis, decreasing the import burdens will also serve to improve and modernize the processing industries. The combinative raw materials strategy already mentioned above, refers to this entire area.

The question is not whether we should develop the processing industry or the mining industry, but whether we should obtain the mineral raw materials for the possible development of the processing industry from domestic mines, or from imports. For the first alternative, domestic mines have to be established and operated. And for the second alternative we must take care of counterbalancing the imports by developing the exporting branches. However, it is characteristic for the present system of values that for example in the case of energy sources, domestic coal mining can be developed for half or one-third of the investments which would be necessary to counterbalance [equivalent] petroleum imports by the products of some export-producing branch of the processing industry. By supplying our energy domestically, the production cost is also lower than in the case of import purchase prices. If we will develop the domestic mining industry in this spirit, we will not be decreasing the opportunities of the processing industry, but--in contrast with relying on the import of energy sources--more of the development resources will remain available for the processing branches.

[Question] Will the number of people employed in mining also have to be increased with the opening of new mines, or will the character of mining undergo fundamental changes?

[Answer] Making sure that we have the necessary manpower is almost as difficult a task as is creating the finances needed to cover the expansion of mining. It would not even be possible to undertake this task without improving the safety of mining and increasing its productivity. However, in order to increase productivity, the industrial background of mining must be expanded to such an extent that it would not hinder the technological level of production.

Using the planned new mining technologies, mining's productivity may increase 2 to 2.5 times the present level of productivity by the turn of the century, including the old operating mines. The amount of raw materials mined will double in terms of tonnage, while employment will decrease in the branch by 20 percent. In the meanwhile the miners will have to become experts in several trades, who feel equally at home operating and maintaining the mining machinery. This growth is part of that unbroken process within the framework of which the generations of miners have created the capacity to meet the economy's raw material needs.

SIX-MONTH FULFILLMENT OF 1980 PLAN ASSESSED

Warsaw ZYCIE PARTII in Polish No 8, Aug 80 pp 1-2

[Article by Stanislaw Gebala, deputy member of the PZPR Central Committee and director of the Central Committee's Trade and Finance Division: "At the Halfway Mark in the Implementation of the 1980 Plan"]

[Text] In evaluating the socioeconomic results of the first half of the year, it should be remembered that we began the current year with very serious stresses on many segments of management. Last year ended with relatively poor results in agriculture, and we failed to meet the planned production targets for a variety of manufactured products, as well as raw and other materials. Taking this into account the National Socioeconomic Plan envisaged a relatively conservative growth rate while at the same time placing the principal emphasis first, on harmonizing economic processes; and second, on increasing management efficiency. The degree to which the social aims of the plan will be implemented was made conditional on reaching these two goals.

Favorable Trends

In analyzing economic growth it is therefore necessary to monitor with equal attention both the completion of actual production tasks and the progress in strengthening stability and forming efficiency trends. In the first half of the current year, and especially in its second quarter, several favorable trends appeared in the economy, among which should be emphasized the generally successful implementation of the plan for the production of nonagricultural materials as well as restraining the unfavorable balance from the second payments area [capitalist countries].

In the period from January to June, 50.4 percent of the annual production plan for goods to be sold by industry was met, and in comparison with the first half of the previous year, that production rose by 7.0 percent. The factor leading to the improvement in the production rate was a significant improvement in the power industry. Interruptions in electrical service to industrial users were incomparably less frequent than in previous years. There was also an easing of transportation problems, which in the

previous year had so seriously hindered both the delivery of raw and other materials and the transportation of finished products from businesses, causing disruptions in supplies. In the first half of the year the basic production of construction and installation businesses grew by 3.6 percent, or 4.6 points more than the plan target.

In the attempts to harmonize the economy, the main effort was directed toward improving the balance of payments to nations of the second payments area as well as toward strengthening the balance of trade. In the first half of the year exports to capitalist countries increased by 30.1 percent in comparison with the same period last year. This should be considered as positive, while nevertheless remembering that the first half of 1979 was characterized by a relatively low level of exports. At the same time, imports from capitalist nations grew at a slower rate, i.e., about 14.8 percent. In fact, for the first time in this decade we attained a favorable balance of trade turnover with the second payments area, i.e., over 600 million foreign-exchange zlotys in the first 6 months. Prices are continuing to increase rapidly on the international capitalist market, while in the first half-year our average export prices rose somewhat more slowly than the prices we paid for imports. This signifies an unfavorable trend for us in the terms-of-trade index.

What Should Be Improved

A rapid, higher-than-planned growth in the population's monetary income during the first half of the year had a negative effect on money-market stability. Its primary cause was the exceeding of the planned wage fund, which in the first half of the year reached 7 billion zlotys. These excesses were particularly sharp in the first months. However, thanks to an improvement in wage discipline in May and June this phenomenon was significantly checked, and this should be regarded as a positive trend.

Exceeding of the wage fund was due primarily to continuing higher-than-planned employment. This exceeding of the wage plan would not in itself have so seriously affected market stability if it had been justified by additional production. However, it is estimated that the 2.6 billion zlotys in wages was not offset by higher-than-planned production results.

Overfulfillment of the payment plan was somewhat compensated for by higher-than-planned deliveries of goods to the market during the first 6 months. Nevertheless, this did not have any influence on relieving the stresses on all segments of the market since the composition of goods delivered to the market was not entirely in keeping with the plan. It is estimated that with respect to goods on three lists, the delivery shortfall in the first 6 months amounted to 12 billion zlotys.

One of the most important segments in which there has been no improvement is the meat market. This is associated with the nonfulfillment of the plan for procurement of slaughter animals. In comparison with the first

half of 1979, the procurement of slaughter animals diminished by 2.7 percent, with a resultant decrease in delivery of meat and meat products.

Despite a certain improvement, there were still numerous stresses during the first half of the year on the economy's materials-equipment supplies. A factor which further worsened the supply situation was the continued efficient management of stocks. A recent review of material supplies revealed a significantly higher level of supply irregularities than was indicated by enterprises which were included in the Chief Central Statistical Office's report at the end of 1979. In the course of the inspection, irregularities in materials supplies worth 41.3 zlotys were exposed. This included 11.8 billion zlotys in unnecessary supplies, and 29.5 billion zlotys in excess supplies.

In the first half of the year, the process of putting the investment front in order proceeded at a rate close to what was planned. Compared with the first half of 1979, investment outlays were reduced by 1.2 percent. Nevertheless, the outlay trend was unfavorable. The growth of outlays for construction and assembly work was too slow, while at the same time purchases of machines and fixtures grew too rapidly. One of the results of this was the increase in uninstalled machines and fixtures. This phenomenon was arrested in June.

The economy's weak point remains considerable inefficiency in implementing investments, leading to serious delays in fulfilling the tasks. During this 5-year period, we are seeing an increase in this phenomenon. The current average cycle of realization of capital expenditures, which in 1975 was 30 months, increased to 36 months in 1978, and to almost 39 months in 1979, despite the fact that in accordance with the assumptions of the plan it should have been shorter in 1979 than in 1975. No improvement has yet occurred in this area in the current year.

Delays in realizing capital expenditures also occur in apartment construction, an area which is of particular social importance. The lowest rate of implementation of the annual construction plan occurred in large urban centers.

All in all, despite the arresting of unfavorable trends in some areas, the state of the economy is still characterized by a variety of shortages and stresses. The leadership of the party openly points to the serious problems with which we are struggling, but which we can and must overcome. In addressing a recent meeting of the active members of the central political-economic committee, the first secretary of the PZPR Central Committee, Edward Gierek, declared:

"...We are dealing with serious problems, but we have considerable means for overcoming them. This requires considered, consistent and disciplined action from all of us. We have a good program of action. It was drafted in resolutions of the eighth congress and is being systematically implemented in government policy."

Implementation of Tasks

The conservation program became an important factor in these activities, as did the Sejm's recent resolution concerning further implementation of the current year's plan. It is worth remembering that the motive for this action and for the subsequently decided-on changes regarding certain tasks and actions of the NPSG [National Socio-Economic Plan] is the fulfillment of production targets in industry and other areas of activity in the face of limited imported supplies while concurrently emphasizing the growth of production based on native resources. These objectives were received with real understanding by ministries, unions and individual businesses. The result is that instead of the initially-planned lowering of industry's production assignments by 60 billion zlotys, adjustments of only 30 billion zlotys were made in the original NPSG targets. And it appears possible that this figure will be reduced during implementation, as indicated by the many initial steps taken by industry.

Foreign trade and market stability will remain areas of key importance in the second half of the year. In both instances, improvement depends first of all, though not only, on fulfillment of plans for material production, especially in industry. It depends not so much on general production increases as on greater discipline in implementing the plan for the structure of manufactured goods. In the first half of the year a significant shortfall occurred in production of goods for export, while at the same time the production plan for so-called remaining purposes was surpassed. Among other things, the actual need by national investors for machines and fixtures was exceeded. Export priority demands that we not only attain the planned quantities, but that we aim to exceed them. Stimulation of exports with a concurrent rationalization of imports is the only way to strengthen our nation's payments position.

The principal direction for growth of Poland's economic cooperation with foreign nations is toward the socialist countries, especially the USSR. The 34th session of CEMA, which took place in June and at which results of cooperation to date were evaluated, indicated new elements for its further intensification. For the second half of the year, the principal task of industry and of the foreign trade apparatus is to take maximum advantage of the possibilities of increasing turnover, particularly of our imports from socialist countries.

In activities aimed at improving supplies for the domestic market we cannot limit ourselves only to fulfilling the planned value of deliveries. The task of strengthening the stability of individual segments has now come to the forefront. What is involved is uncompromising adherence to the plan for the volume of goods to be delivered, as well as assurance of continuity of sale of basic food products and consumer goods. There are potential sources of additional production of a variety of market articles. These are, for example, the furniture industry, light industry, all types of cooperatives and other enterprises which are capable of producing goods

for the market, but have not yet done so. Increased labor-intensiveness is often necessary to take full advantage of these capabilities, and with it there are additional costs. The department of domestic trade is working on balancing these needs. They will be covered by, among other allocations, 450 million zlotys from the wage funds of the Committee for Market Affairs. Judicious spending of this fund may yield 2 to 2.5 million zlotys. The departments and cooperatives concerned have worked out concrete plans for increasing production of market goods, including food.

Cheaper Means More

The basic condition for accomplishing the targeted tasks in the second half of the year, as in future years, remains increased management efficiency. We have not noticed significant progress in this area in the first half of the year. Comprehensive efficiency measures must lead to fuller use of all production resources. Raw and other materials are the relatively scarcest elements of production at present; their shortage in many instances limits the degree to which production capabilities may be taken advantage of. We must intensify efforts to lower material-intensiveness, whose level is still excessive. There are also considerable reserves of inadequately-exploited labor resources. In comparison with 1979 there was an increase in the first 6 months of the current year in absences due to illness, as well as unjustified absences, and almost 10 percent of the nominal work time is unworked. We must manage our wage funds more wisely.

The most important point is to assure that while businesses aim at fulfillment of actual production plans, they at the same time aim at lowering the costs of production. In the plan for the current year, thanks to the decrease in individual consumption and the resultant decrease in material costs, the combined savings in industry and construction amounted to approximately 25 billion zlotys. This is a sum which may have substantial influence on limiting production costs and, indirectly, prices.

While working on lowering costs, it is essential to pay closer attention to the extreme losses whose totals tend to be increasing, indirectly reflecting the scale of the various irregularities in the operation of businesses. We must make the public clearly aware that the national income must be increased through a reduction in costs, in effect providing greater resources for consumption and development.

The tasks facing the economy in the second half of the year are not easy. The solution to current social problems will depend on the degree to which these tasks are fulfilled, as will the starting point of the new five-year plan.

PROBLEMS IN IMPLEMENTING HOUSING CONSTRUCTION PROGRAM DESCRIBED

Warsaw INWESTYCJE I BUDOWNICTWO in Polish No 7-8, Jul-Aug 80 pp 13-16

[Article by Aleksander Kapustka]

[Text] Among many vital problems discussed both in the pre-Congress discussions and during the deliberations of the Eighth Party Congress, implementation of the long-range housing program, one of the most important goals of the socioeconomic policies of the 1970's and 1980's. occupied a prominent place.

The housing program, comprehensively prepared and formulated in a resolution of the Fifth Plenum of the PZPR Central Committee and in a Sejm resolution dated October 19, 1972, set housing requirements for the 1970-1990 period at 6.9-7.3 million dwellings. This program, according to Environmental Development Institute forecasts for the individual five-year plans, is shown in the following table.

Table 1. (In thousands of dwellings)

(1) Lata	(2) Ogółem	(3) Miasto	(4) Wieś
1971—1975	1140	850	290
1976—1980	1550	1300	250
1981—1985	2150	1700	450
1986—1990	2430	1850	580
1970—1990	7270	5700	1670

Source: A. Kapustka, "The Substance and Time Frame of the Investment Process," Zielona Gora, 1978, p 23.

Key:
1. Years
2. Total
3. City
4. Village

This shows that 2,690 thousand dwellings were envisaged for the first ten-year plan, while during the second ten-year plan, 1980-1990, 4,580 thousand dwellings are to be built. The State's efforts in implementing the housing program as shown above were concentrated on preparing the

indispensable construction potential of erection-assembly enterprises, building prefabricated-elements factories and modernizing and expanding many industrial plants closely connected with the housing industry.

During 1971-1975, investment outlays for municipal and housing construction amounted to 326 billion zlotys, 71 percent more than during 1966-1970.

During the past five-year plan, 1,125 thousand dwellings, with a total floor space of 63 million square meters, were built. The plan goals set for 1971-1975 were fulfilled 104.2 percent, thus implementing 15.4 percent of the long-range construction plan projected to 1990. In comparison to the prior five-year plan, housing increased by 183,000 dwellings. The average size of dwellings also rose, from 42.8 square meters in 1970 to 47.1 square meters in 1975.

For 1976-1980, construction of 1,575 thousand dwellings was planned, including 1,193 thousand dwellings for socialized construction and 382,000 for individual construction. In addition, construction of 1,307 thousand dwellings for the non-agricultural population and 268,000 dwelling for the agricultural population was projected.

In comparison to 1971-1975, the present five-year plan envisages an increase of 450,000 dwellings, including 390,000 for the non-agricultural population. This large increase in planned housing construction is possible because of the completion, during 1971-1975, of 87 factories producing large-panel elements, and the construction, by 1980, of 79 house-construction factories.[1] The total production capacity of the prefabricated-elements factories, up to 1979, was 13.2 million square meters of dwelling space annually.[2]

Despite such large outlays allocated for increasing construction potential during 1976-1979, the annual housing construction plans were not fulfilled, especially multi-family construction for the non-agricultural population. During these four years, 73.7 percent of the five-year plan was fulfilled, with completion of approximately 1,161 thousand dwellings. Thus, for the last year of the current five-year plan, 414,000 dwellings remain to be built, or 26.3 percent of the plan goals for the entire five-year plan. The situation here is worsened by the fact that the largest backlogs arose in the large urban centers, such as Gdansk, Katowice, Wroclaw and Warsaw, where housing requirements, due to development of industry and services, are most critical.

---

[1] M. Wawrzeniuk, Eighth Plenum, PZPR Central Committee, "Assessment and Developmental Trends in Housing Construction," INWESTYCJA I BUDOWNICTWO, 1977, No 9.

[2] Eighth PZPR Party Congress, "Basic Documents and Materials," KiW [Ksiazka i Wiedza], Warsaw, 1980, p 27.

It should be noted that during this period average floor space in dwellings increased by five square meters since 1975 and now totals 52 square meters in socialized construction. As a result, density rate per room dropped from 1.21 people in 1975 to 1.06 in 1979.

Another problem revealed itself during the current ten-year plan: lack of the facilities that must accompany housing construction, the social service facilities. The backlog from the 1970's, which amounted to 1.3 million square meters of floor space, increased by 45,000 square meters during 1971-1975. The plan called for 1,313 thousand square meters of floor space, but only 1,268 thousand square meters were completed.

Outlays for technical infrastructure were greatly increased during 1971-1975. They amounted to 154.7 billion zlotys, compared to 86.2 million zlotys during the preceding five-year plan. Despite the high growth rate of investment outlays for municipal management and expansion of basic technical infrastructure, provisions were not made in advance for land development. As a result, the share of land development taking place concurrently with housing construction is growing. In 1975 this share averaged 11 percent nationally; in 1976 it rose to 31 percent; in 1978 it was 40 percent; and it now stands at approximately 53 percent.[3] The above situation has a dysfunctional effect on efficient implementation of housing construction, because enterprises that are working on technical infrastructure and buildings on the same construction site frequently get in each other's way.

In accordance with the Eighth Congress directive, 1,700 thousand dwellings will be completed during 1981-1985, including 150,000 by modernization of existing resources. Reduction of investment outlays in the next five-year plan does not mean that the general policy of ensuring each family its own dwelling in the 1990's is being abandoned.

During the 1970's, the share of outlays for the housing industry, construction materials, land development and heating-plant systems in the entire national investment increased from 19 percent in 1971 to 30 percent in 1980. During 1971-1979, 144 house factories were built, which means that outlays now allocated to the overall housing industry can be designated for production of indispensable materials and finishing products. However, better use must be made of existing production potential in the industries co-producing with the construction industry.

Thus there must be a decided improvement of management efficiency in every sector in the 1980's. This is imperative not only because party resolutions and administrative orders mandate it, but also because internal and external conditions related to economical management of materials, raw materials and energy demand it.

---

[3] W. Dabrowski, "Current Tasks in Housing Construction," NOWE DROGI, 1979, No 7 362, p 48.

The Eighth Party Congress outlined the strategic courses of action for the next five-year plan. It also committed all party and administrative units to broader action aimed at full implementation of the program outlined.

To implement the investment process, the party's resolution require:

-- improvement in operation and efficiency of investment processes,
-- increase in work-shift rate in the building materials industry,
-- a higher level of operation and utilization of machinery, equipment and transport means,
-- reduction in unit standards of materials and raw materials consumption and improvement in materials management efficiency and inspection of on-site materials consumption,
-- reduction in implementation cycles,
-- improvement in construction quality,
-- reduction in prime costs,
-- increase in labor productivity by improvements in organization and elimination of manual labor,
-- wider application, in addition to large-panel technology, of other material-conserving and energy-conserving technologies that would permit better utilization of the production capacities of construction-materials plants and of local raw materials,
-- strengthening of the role of the investment plan, increased financial discipline and increased efficiency in the inspection system,
-- improvement in economo-financial instruments in order to more effectively enhance public management efficiency.

It appears from the above that to ensure implementation of the primary socio-economic goals, broadly conceived organizational and techno-economical incentives must be skillfully introduced into management practice.

As concerns improvements in organizational efficiency, in accordance with the Party Congress' decision, a broad assessment of the economo-financial system's present state of planning, management and functioning must be made. Past analyses have shown that the main source of inefficiency in the investment process is improper organization and management, excessive splitting-up and formalization of all decisions, inflation of organizational structure on all levels and lack of proper coordination.[4]

An important factor interfering with the efficient course of the investment process is the failure to observe scientific organizational procedures, especially underrating the preparation stage in the investment process, to which much more effective labor time should be allocated than has been done heretofore (the author's studies show that 37-42 percent of effective labor time should be allotted for this purpose).

---

[4] A. Kapustka, "Investment Paradoxes," PRZEGLAD TECHNICZNY-INNOWACJE, 1978, No 3 and "Organizational Dysfunctions in Investment Processes," PROBLEMY ORGANIZACJI, 1979, No 2.

Only after mistakes in the investment process are completely diagnosed can specific efficiency-promoting suggestions be developed. It appears that the ultimate aim, particularly in relation to the smaller voivodships, which will be most appropriate to local needs and capabilities, will be an organization of voivodship general construction plants. Such an organization would be in accord with the text of the PZPR Central Committee report presented at the Eighth Party Congress and would comply with the main trends of the already-begun decentralization of certain powers to the voivodes.

A great deal of improvement in construction is possible by selecting the proper technology for construction of buildings, their location, number of stories, by economical and efficiency management of materials and energy and utilization of on-site equipment, etc. According to W. Bien's [5] studies, traditional (cheapest) technology's share has dropped from 12.7 percent in 1970 to 1-2 percent in 1980; large-block construction also dropped, from 60 percent to 11 percent. These technologies are being replaced by the large panel, which is also the most expensive. In 1980, 80 percent of all buildings will be built using large panels. Apart from the emergence of a so-called monoculture in Polish housing construction, the investment cost of large-panel technology in housing construction is too high. One solution would be the introduction, to a larger degree than in the past, of a monolithic technology, which is more economical from the standpoint of materials consumption. It provides, for example, a 50 percent savings in cement, 20 percent in steel, and also in transport and manpower.[6]

From among many technical factors we will indicate still one more, namely the share of multi-family buildings over five stories high, which increased from 31 percent in 1970 to 44.4 percent of total construction in 1978. Aside from higher construction costs (an average of 20 percent), maintenance costs of multi-story buildings are also higher: 30 percent more for 6-10 stories, 25 percent more for 11-13 stories, and by as much as 60 percent more for buildings over 14 stories.[7]

It is not possible to discuss in one article the effect of other technical factors in promoting better utilization of materials and raw materials, better utilization of construction equipment, elimination of stoppages at many construction sites for various reasons. There is much room for improvement here.

Serious losses in construction occur as a result of poor quality of construction and the necessity for corrective work. Such losses are estimated at

1 to 5 percent of total costs, which indicates the seriousness of the problem. The problem of quality in all construction, so strongly emphasized during deliberations of the Eighth PZPR Congress, requires more searching analysis. The quality of construction-assembly work, finishing work, etc., is affected not only by the work of the builders themselves, but also by the work of many enterprises supplying poor-quality raw materials, other materials and technical equipment. This situation will not improve merely by publishing more rules,[8] which are not being observed.

In the author's opinion, improvement in quality of housing construction requires basic changes in inspection and control.[9]

Improvement in quality of construction-assembly work and materials requires a number of actions, starting with planning, which also includes comprehensive indexes on quality, durability and reliability of materials and equipment and a system of rewards and vocational training.

The housing construction program is, in accordance with an Eighth Congress resolution, a political program aimed at solving an acute social problem, There is no place in this program for any kind of waste or lack of efficient management.

In implementing the socioeconomic strategy outlined by the Eighth Party Congress, the human factor, its attitude and commitment, and receptivity to innovations, will have a deciding influence.

Motivation, in the broadest meaning of the word, is a very important problem in developing a creative attitude, both in the managerial staff as well as in all enterprise personnel. The task of the motivation system should principally be the integration of all enterprise personnel towards implementing the assigned main goal by coordinating and directing the individual goals of its members. The broadly drawn motivation system should allow for initiative, ingenuity and commitment of the personnel. It should encourage the managerial staff to introduce innovations, apply modern management methods, take risks in management operations, etc. Very often the motivation problem, both in practice and in literature, is confined to the economic sphere, particularly to wage incentives. Without minimizing the value of economic instruments, such opinions should surely be regarded as improper for they simplify the problem. J. Pajestka's statement appears

---

[8] In addition to the construction code, Government Presidium decision No 42/77 dated April 15, 1977 was recently issued on improving housing construction quality, and also a law dated February 8, 1979 on quality of construction produces, services, works and buildings (Law Journal, 1979, No 2, item 7).

[9] This subject has been discussed in another article: A. Kapustka, "Quality Control in Housing Construction," INWESTYCJA I BUDOWNICTWO, No 4, 1980.

to be correct when he writes: "Reducing motivation factors simply to narrowly conceived material incentives is a damaging simplification and even distortion, undermining not only the meaning of socialism, but also the meaning of those human values that shaped the modern civilization."[10]

The motivational driving force under socialistic conditions is the striving for humanization of labor and for society's ever-fuller participation in the process of efficient management and creation of the future. The basic condition for success in implementing the investment process should be skillful cooperation with personnel, creating a climate of joint responsibility of the entire working collective for implementation of investment, replacing rigid orders and prohibitions with positive incentives, both moral and material. A positive role can be played here by consistent management and direction of working teams using a method described in the literature as "management by objectives." Implementation of investment as an all-social objective is announced to individual working teams, allocating them means and powers. Partial objectives should be accurately formulated also from the quantitative standpoint, and then a responsible accounting of their performance should be made according to the same rules.

Humanization of labor, about which so much has been written lately, is also the adjusting of working hours to actual conditions, good organization in transporting workers to the job site, creating proper living conditions for them, ensuring complete work safety, etc.

To motivate working teams by using economic instruments, it is necessary first of all to clearly define the bases for calculating rewards for performing a task. Any complications or inconsistencies in this area cause needless bitterness and alienation of workers. By way of example, the rewards for workers paid by the flat piece-rate system should not be changed, regardless of the amount of money earned by the work gang if it is doing its job properly. The measure here should be that the assigned job is done on time, of good quality, and with materials savings.

Responsible introduction of a motivation system should include all participants in the investment process, and particularly the contractors, suppliers of machines and equipment, the design offices, and investors. Such a broadly conceived investment process systems motivation will help reduce the red tape between these units, eliminate needless documentation, cost estimates and copious correspondence, and create "psychical bonds" which will have a positive effect on harmony in investment implementation.[11]

AGRICULTURAL DEVELOPMENT IN 1950-80 PERIOD REVIEWED

Bucharest REVISTA ECONOMICA in Romania No 31, 1 Aug 80 pp 5-7

[Article by Oprea Parpala: "23 August 1944--23 August 1980--A Period of Profound Transformations and Superior Results in Romanian Agriculture"]

[Text] Thirty-six years ago the Romanian people set out on a fundamentally new path of socioeconomic and political construction--the path of socialist revolution in all domains of activity. In those years radical changes have taken place in the whole socioeconomic configuration of the country, essential mutations have occurred which have propelled the economy and the Romanian society to hitherto unknown levels of progress and civilization.

The historical event of 23 August 1944 opened radically new perspectives for the modernization and accelerated progress of agriculture, thus laying the cornerstones for its socialist transformation. At the same time it should be stressed that the basically new elaboration of the Romanian concept of socialist agrarian policy took place at the Ninth RCP Congress on the bases of the reconsideration of the role and the functions of agriculture in relation to the whole economy, the objective of transforming agricultural labor into a form of industrial labor and the content, the necessary stages and the ways of carrying out a profound agrarian revolution in Romania, which would contribute substantially to the economic and social progress of the country, to the prosperity and happiness of the people.

From Quantitative Accumulations to Qualitative Transformations

The Ninth RCP Congress took place at a moment in which--as early as 1962--the socialist relations of production had been generalized in Romanian ag agriculture. In this context the concept appeared according to which the full and final victory of socialist production relations in the villages was considered to be the conclusion of the socialist agrarian revolution with the result that the new, socialist relations, by their nature alone, would automatically prove their superiority, generating ever greater yields

and superior economic efficiency. Applied in practice, such an understanding of the content of the socialist agrarian revolution would have doomed Romanian agriculture to technical backwardness, to development at a snail's pace, which, consequently, would have deepened the differences (contradictions) between industry and agriculture, village and city, between workers and peasants. As a matter of fact, during the 15 years before the ninth congress, agriculture received limited investment funds and certain phenomena of distrust in the peasant's capacity to use modern technology, based on chemicalization, irrigation and mechanization, also manifested themselves.

It is the historical merit of the RCP secretary general Comrade Nicolae Ceausescu, that, beginning with the elaboration of the documents for the Ninth RCP Congress, he militated with vigor and creative thinking for the implanting of a new concept of agrarian development in socialism, a concept according to which the socialist agrarian revolution does not end with the victory of the new production relations, but has to be continued and supplemented naturally by revolutionizing the technical and material base of agriculture, the methods and forms of organizing labor and directing production, according to the stage attained in the development of the factors of production, by perfecting the relations of production on a continuing basis. Such a concept of the ways to carry out a profound agrarian revolution also corresponds to the direction of the evolution of the population agricultural land ratio. But, under the conditions prevalent in Romania, demographic growth surpasses by far the possibilities for expanding the agricultural area (with trends toward reducing the land supply per capita). At the same time, the sharp decrease in the population involved with agriculture increases the portion of agricultural land per person working in this branch. The combined influence of the two factors can lead to only one logical and necessary effect: an increase in investments per unit of land in order to increase continuously both the yield per hectare and the technical equipping of agricultural labor, to raise labor productivity at least in accordance with the increase in land per person working in agriculture.

This is why the 1965-1980 period is, first of all, a period of significant quantitative accumulations in expanding and modernizing the technical-material base of agriculture. This new reorientation was based upon a consistent investment policy (mainly of state funds but also of the funds of the agricultural units) which insured the technical progress required by this branch: mechanization, chemicalization, irrigation, development of animal breeding, production of high-quality seeds, planting material and reproduction animals.

We believe that, in order to appreciate the dimensions of this increase, the figures in Table 1 do not require any comments. They reflect, without any doubt, the progress in developing the technical-material base of our agriculture. A number of other considerations support this idea.

Table 1. Evolution of the Technical-Material Base of Agriculture During the 1950-1978 Period

* 1975 Source: Statistical Yearbook of the Socialist Republic of Romania, 1979, Central Directorate for Statistics

During the 1965-1978 period the investments allocated to agriculture were over 200 billion lei, which is about 3.5 times the investments during the whole 1951-1965 period. On that basis, a strong increase was registered in the technical equipping of labor (no matter which element we are referring to--fixed funds, traction power, consumption of chemical fertilizers, irrigated area or numbers of production animals. If, as far as the consumption of chemical fertilizers per hectare of arable land is concerned, Romania has gone half-way toward reaching the level of the developed countries; according to the size of the irrigated area and its proportion to the total arable land, Romania holds one of the first places in Europe.

But, it would, to say the least, be erroneous to measure this period only by the quantitative achievements since, at the same time, significant qualitative transformations have taken place too. As a matter of fact, the very objective of our future development--to achieve a new quality in all domains, including agriculture--does not exclude, but requires, the existence of qualitative changes which have already been made in the course of the development of agriculture to date. We will mention only a few of them.

Thus, the slight expansion of the agricultural land was mainly achieved through the most intensive categories of use (such as vineyards and orchards), marking a qualitative improvement in the use of soil. The same tendency, toward new quality, was also indicated by the structure of the cultivated areas. The reduction in the areas planted with grains was accompanied by the expansion of those cultivated with technical- and leguminous plants. The modifications registered within various crop groups confirm the same qualitative orientation. Within the grain crops, while maintaining the priority given to growing seed corn, barley has started to expand. There was a considerable expansion in the category of the leguminous seed crops, soybeans and in the technical crops group, sugarbeets and sunflowers. Significant changes took place in the fodder crops, with an increased share of the perennial leguminous crops (lucerne and clover). The expansion of fruit-tree and vine plantings was made under the circumstances of clearing large surfaces from the old plantings and reestablishing intensive plantings.

Generally speaking, the quantitative increase per unit of land of all elements of the technical-material base of agriculture brought about important steps toward qualitative transformations, since it gave agricultural production an increasingly intensive character. The qualitative element manifested its presence in the whole process of quantitative accumulations in our agriculture. For example, the structure of investments shows a tendency to increase the share of those investments intended for the active part of the fixed funds (equipment and machines) and to decrease the share of investments for constructions. In the structure of the traction power, the machine traction has become

predominant and, within it, an increase in the share of the means of transport and stationary engines intended for zootechny and irrigations, has been registered. Important sectorial changes also took place in the structure of fertilizer consumption, in the favor of the cooperative sector of the agriculture, with a view to standardizing the conditions of production on a given territory. The liquidation of the big discrepancies in distributing the consumption of chemical fertilizers, territorially and for crops was also started, and a more balanced ratio among nitrogen, phosphorus and potassium was assured at the same time. Setting up land for irrigations both the obtaining of a rational proportion between the big systems and the local systems and the use of more economical methods of irrigation are considered. In the field of animal raising an increase on a priority basis of the meat-producing species and categories is noted. At the same time, research and production were oriented toward the creation and use of new varieties and hybrids of plants and toward the improvement of animal breeds, in order to increase their production potential.

Professionalization of the Labor Force

Under the impulse of the development of the whole national economy and of the increase of the technical-material base of agriculture, the agricultural labor force has registered a double process: a (absolute and relative) reduction and an increase in professional training.

The significances of the accelerated decrease in the population involved in agriculture are multiple, but the transformation of simple work into complex work is of special interest. The decrease in the population involved in agriculture (see Table 2) is not a simple quantitative transfer, but implies important quantitative transformations for the population left to work in agriculture because its decrease in number takes place in the framework of an increase in the technical endowment of the agricultural work--which, in its turn, requires an increase in the technical training of all agricultural workers especially since the new technology is also generating new trades. We have in mind not only such "top" professions in the villages like those of tractor driver or agricultural mechanics, but also those which concern the large mass of cooperative members: animal tenders, vegetable growers, fruit-tree growers, horticulturalists, etc. This is the reason why the problem of developing and improving agrozootechnical mass education has become a component (approved by law) of agrarian policy in our country, permitting a qualitative leap from the former individual peasant to the new peasant, a specialized agricultural worker, who cooperates in the work process with the other agricultural workers.

At the same time, agricultural specialists (with intermediate and higher studies) have a decisive role in rationally organizing production, in using modern technologies with a view to increasing production and efficiency. This also explains the special attention paid to the equipping

Table 2. The Agricultural Labor Force During the 1950-1978 Period

*Data refer to year 1960

of agriculture with an ever larger number of specialists, so that, today compared to 1965, an agricultural specialist with higher studies is responsible for an area half the size. Among these, a special place is occupied by the research cadres, creators of new varieties and hybrids of plants and improvers of native animal breeds, as well as the teaching staff whose links with production contribute to the raising of the level of development of the whole agriculture.

The Constant Perfecting of Production Relations

The scientifically based agrarian policy starts with the idea that the development of production forces also necessitates the perfecting of production relations, permitting a more efficient use of the production forces. In this context, our agrarian policy, established in a superior way at the ninth congress of the party, on the basis of the idea that the agricultural enterprises (state-owned and cooperative) remain the basic units of the agriculture, encouraged and supported the expansion and development of various forms of cooperation and association in work and production, up to the superior forms currently established by statute in the form of the intercooperative economic association or of the

association (cooperation) between the agricultural production cooperatives and the state units or the consumers cooperative units. Apart from the positive economic effects, thanks to increased possibilities for developing production forces, these new forms of association make their contribution to the appearance of new, more comprehensive, forms of ownership in agriculture: intercooperative ownership, in the case of the intercooperative economic associations; joint state and cooperative ownership, in the case of an association (cooperation) between the CAP (agricultural production cooperatives) and state units. Such new elements of the agricultural patrimony represent important steps towards bringing closer and transforming the two forms of ownership in our agriculture-state and cooperative into the property of the whole people.

The same priority objective under the circumstances of bringing closer, in advance, production conditions in the CAP and the IAS (state agricultural enterprises) is pursued by the constant perfecting of the leadership bodies of agriculture. The united state and cooperative agroindustrial councils (which have their roots in the specialized territorial councils and, then, in the intercooperative councils) are the specific form, according to Romanian conditions, of economic and social integration in agriculture.

The Consequences of the Policy for Modernizing Agriculture

The revolutionizing of the technical-material base of agriculture, under the circumstances of the raising of the professional training of all agricultural workers and of providing an ever larger number of agricultural specialists, had a positive influence on the increase of labor productivity and, of production, and on increasing the contribution of agriculture to the increase in the national revenue, to the improvement of the living conditions of the whole people etc.

The quantitative increases (see Table 3) were, in this respect also, accompanied by qualitative changes. In this way, labor productivity has become the main factor for increasing agricultural production, giving our agriculture the essential features of a modern agriculture: Moreover, in its average annual rate of increase of overall agricultural production (6.0 percent during the 1966-1978 period) Romania holds one of the first places in the world. At the same time, the more rapid growth of zootechnical production as against the vegetable production expresses the qualitative changes occurring in the structure of overall agricultural production, by increasing the share of animal production (from 36.3 percent in 1965 to 44.3 percent in 1978), which is becoming and should become the priority branch of Romanian agriculture.

[illegible] most obvious proofs of the qualitative transformations occurring in the evolution of the Romanian agriculture is its increased contribution to the growth of the national revenue.

1) Average for 1951-55; 1961-65; and 1976-78; 2) 1950, 1965, 1978; 3) 1970

The development of the production forces, under the circumstances of perfecting production relations has allowed a steady and balanced increase of the production in all the specific branches and sectors of Romanian agriculture, with a view to assuring the complete self-supplying of the population's consumption, on the basis of scientifically substantiated norms. Thus, grain production (mainly, corn and wheat) has continued to receive special attention, as being the pivot around which all the other agricultural sectors are developing (especially animal-breeding). The need to improve the structure of food consumption by developing intensive branches, specifically for Romanian agriculture has led to a significant increase in the production of vegetables, grapes and fruits. Within animal production, a significant increase has been recorded by meat production, as a basis for improving the structure of the population's food consumption.

The qualitative changes registered in the structure of agricultural production were, naturally, reflected also in the structure and evolution of the production and of the consumption of the main agricultural products per capita. While potato consumption remained almost the same, and grain consumption decreased, the consumption of vegetables and fruits, especially meat and eggs (suppliers of protein of animal origin) have registered the largest increase. If, in its per capita production of various agricultural products (first of all, grains) Romania is close to the level attained by the developed countries, the evolution of the food available each day per capita (in calories and grams of protein) situates our population among the peoples of the world best provided with food resources, this being a guarantee for developing a vigorous people, with a work capacity (physical and intellectual) up to the level of the demands made by the present technical and scientific revolution.

The increase of the production capacity of Romanian agriculture is also attested to by the increase in goods available for export, especially as processed food commodities, with a higher export efficiency.

In conclusion, the 1950-1980 period is the period of a special dynamism in the development of Romanian agriculture, the period in which the significant quantitative accumulations in developing the technical-material base and training specialists gave rise to qualitative changes, a premise for the transition--in the 1981-1985 five-year plan--to a new quality, which took concrete form in a substantial increase in harvests and agrotechnical yields, in the elevation to a superior level of the economic activity carried on in this basic branch of the Romanian economy.

ROMANIA

PROVISIONS OF FOREST CONSERVATION, DEVELOPMENT PROGRAM

Bucharest REVISTA ECONOMICA in Romanian No 34, 22 Aug 80 pp 15-16, 19

/Article by Viorel Hampu and Petre Cioclu: "A Resource That Must Be Exploited and Used as Efficiently as Possible: Wood"/

/Text/ On the basis of the decisions of the 11th party congress, on the initiative and instructions of the secretary general of the party, Comrade Nicolae Ceausescu, there was drawn up the National Program for the Conservation and Development of Forest Resources in the 1976-2010 Period, which, after being subjected to public discussion, was adopted by means of Law No 2/1976. The program contains, in a unitary view, the measures that are required in order to rationally manage the forest holdings, to introduce a normal rate of cutting and regeneration of the forests, to raise their productivity, to improve the protective functions of the forest. The implementation of the measures in the program will provide for the practicing of intensive silviculture, the raising of its contribution to the development of the national economy, to the conservation of the environment.

We present below an analysis of the way in which the main tasks contained in the program with regard to forest management are being fulfilled and the results obtained in the years that have passed since its adoption.

A First Component: the Area and the Structure of the Forests According to Species

One of the most important provisions of the program refers to maintaining in the future the forest resources at least at the current area. This provision has been and is being fulfilled, so that at the start of 1980 the area of the forest resources was 6,334,000 hectares, 14,000 hectares more than the program's provisions for this year. The respective situation is due to the greater exigencies of the forestry units with regard to requests for removal of land from the forest resources for the needs of other sectors of the national economy (investment objectives, overhead powerlines, drilling and so on), as well as to the entry of land from the agricultural resources--unfit for farm crops, vinegrowing and fruitgrowing--into the composition of the forest holdings, which has counterbalanced the removals.

The task concerning the afforestation of land denuded by means of current cutting, of degraded land taken over from agriculture and of land earmarked for the planting of forest vegetation is also being fulfilled. These good results have also occurred due to the fact that both the areas that were to be afforested and the material resources needed for achieving them have been provided by means of the sole national plans for economic and social development. According to kinds of land, one finds an overfulfillment of the afforestation in the forest resources by 11,900 hectares (including 9,500 hectares by the units of the Department of Silviculture) and a total underfulfillment of 5,900 hectares in the unproductive (degraded) land outside the forest resources (including 6,600 hectares in the land held by the CAPs /agricultural productive cooperatives/ and others in zones without cooperatives) (see the table). It is necessary that the present holders of degraded land proceed at once to utilize it, especially for agriculture, and that, when this is not possible, it be afforested--with the help of the forestry bodies--so that no square meter of the homeland's territory remains unutilized.

The orientation contained in the program with regard to improving the structure of the country's forests according to species has also been followed in the sense that the afforestation with coniferous trees has been preponderant (73 percent in the forest resources administered by the Department of Silviculture, as compared with the 70 percent stipulated as a target), which will provide for an increase in the proportion of coniferous forests to 40 percent in the next 30-35 years, as compared with the 28 percent that it was in 1975. In this way, it will be possible to satisfy more and more fully the national economy's need for coniferous wood, especially for the production of cellulose.

Within the afforestation done, the restoration of poorly productive forests (700,000 hectares on the date of preparation of the program) has been continued by means of their replacement with new, vigorous, high-yield plantings. The results obtained between 1976-1980 (120,700 hectares) surpass the average annual rate of 22,000 hectares stipulated in the program. The restoration of this area has been achieved mainly through afforestation with fast-growing species, which will lead to the obtaining of an output 2-3 times higher on that area and to a rise in lumber production from 30-40 percent, as it is at present, to 75-80 percent.

In order to be able to satisfy the growing need for pulpwood as quickly as possible, the program provides for the continuation of the creation of special crops for this assortment, so that by 2000 a total area of 450,000 hectares will be reached. The target that applies to the 1976-1980 period (74,000 hectares) has been fulfilled and even overfulfilled by 4,200 hectares. The advantage of the specialized crops for pulpwood--for which selected seedlings are utilized--resides in the fact that they will be able to be harvested at an age of 30-50 years for coniferous trees and 15-20 years for soft deciduous trees, as compared with 100-120 years and 20-25 years, respectively, in ordinary forests, thus resulting in a rise in

production of 6-8 cubic meters per year per hectare for coniferous crops and 8-10 cubic meters per year per hectare for deciduous crops.

Table: The Degree of Achievement of Afforestation in the 1976-1980 Period

	Unit of measure	Stipulated	Expected	%
1. All afforestation--total	thousands of hectares	278.0	284.4	102.3
Of the total, according to kinds of land:				
In the forest resources--total, including by:	thousands of hectares	234.0	245.9	105.1
The units of the Department of Silviculture	thousands of hectares	208.0	217.5	104.6
The Danube Delta Central	thousands of hectares	2.7	2.7	100.0
P People's councils	thousands of hectares	23.0	25.7	111.7
In unproductive (degraded) land outside the forest resources--total, including by:	thousands of hectares	37.0	31.1	84.1
The units of the Department of Silviculture	thousands of hectares	17.0	17.7	104.1
The present holders (CAPs and others in zones without cooperatives)	thousands of hectares	20.0	13.4	67.0
Along roads and watercourses--total	thousands of hectares	7.0	7.4	105.7
2. The structure of the afforestation according to groups of species in the forest resources administered by the units of the Department of Silviculture--total, including:	thousands of hectares	208.0	217.5	104.6
Coniferous trees	thousands of hectares	149.4	158.8	106.3
Percentage of the total	%	71.8	73.0	
Deciduous trees	thousands of hectares	58.6	58.7	100.2
Percentage of the total	%	28.2	27.0	
Of the total, fast-growing species (coniferous and deciduous trees)	thousands of hectares	133.5	134.5	100.7
Percentage of the total	%	64.2	61.8	

It should be mentioned that in afforestation the valuable indigenous species, adapted best to the soil and climatic conditions in our country and having a high industrial value, (spruce, fir, oak, durmast, ash, sycamore maple and so on) and other species that are suited to the natural conditions in our country (larch, pine, Douglas fir and so on) have been

promoted for cultivation. The genetic certification of all afforesting material was introduced in 1978 in order to provide for the growing of stands with increased viability, greater resistance to harmful factors, and higher productivity.

A Second Component: the Tending of the Forests as a Factor in Increasing Their Efficiency

The forest takes a long time from its creation to maturity. If in this interval the process of development of the forest is left only under the influence of the laws of nature, there arises the situation that low-quality trees with a low economic value grow in the forests. In order to prevent such a situation, forestry science and practice have established a complex of activities for tending the plantings and stands--clearing, pruning and thinning--which have the role of eliminating the unsuitable specimens during the forest's development, of favoring the growth of vigorous trees, in optimum densities, with high-quality wood, so that at logging time the productivity and the value of the output per hectare are maximum. For the 1976-1980 period, the program provides that annually an area of 280,000 hectares of forest is to be covered with tending work, a target that was fulfilled by 1979 with an average annual overfulfillment of 4,000 hectares, an overfulfillment that is expected to be maintained in 1980 too.

In order to provide a suitable state of plant health in the forests, sanitary cutting--fallen, broken, dead, insect-ridden and wind-toppled trees--has been done on an average annual area of 1.2 million hectares, as compared with the 1 million hectares stipulated in the program. In this way, large quantities of timber utilized in industry or as fuel in rural areas have been extracted and brought into the economic circuit.

Although the program's provisions concerning improvement and sanitary cutting have been fulfilled, one still finds forests in which the tending operations have not been performed at the necessary level, due to the fact that at present the density of forest roads per hectare of forest is still below the optimum level. The problem will find its solution in proportion to the construction of forest roads, the growth of the accessibility of the country's forests, which would permit the application of tending and sanitary measures over the whole area of the forest resources under as economical conditions as possible. The combating of pests (defoliating caterpillars, bark and wood beetles and so on) has constituted a constant concern within the action of systematically tending the forests. To this end, in accordance with the provisions of the program, action has been taken to identify and combat them in due time, to apply projects for preventing their appearance en masse. It should be noted that the modern methods of combating them have been expanded: the biological method with biopreparations (2,800 hectares at the level of 1979), the methods with pesticides having selective properties and a low degee of pollution (4,200 hectares) and chemical treatments with small doses per hectare of forest (90,400 hectares).

Special attention within this work has been devoted to preventing the multiplication of bark and wood insects in the zones with wind- and snow-toppled trees in the coniferous forests in which such natural disasters have been registered in past years. By this means of acting, the proper development of young stands and a good state of plant health in all forests in the country's forest resources have been provided.

A Third Component: the Rate of Cutting

In order to increase the volume of logging in the future, the program provided for the limitation of the annual cutting to 20 million cubic meters of raw timber "on its feet" in the 1976-1985 decade, including 16 million cubic meters of main products and 4 million cubic meters of byproducts from thinning. The actual cutting in 1976-1979 and the preliminary cutting in 1980 are situated, as an annual average for the 1976-1980 period, 500,000 cubic meters below the stipulated level.

Concomitant with keeping within the planned annual quota of the volume of cutting, the aim has been, in the as near future as possible, to correlate the logging operations with the forest's possibility not only on the scale of all the forest resources but also on the level of each of the 2,200 production units--a basic technical unit in organizing the production of wood in silviculture--into which the forests administered by the Department of Silviculture in the MEFMC [Ministry of Forestry Economy and Construction Materials] are divided. The results obtained thus far, although they have improved the situation, are still far from being satisfactory. Thus, while in 1975 the volume of local excesses (at the level of the production units) totaled 5.5 million cubic meters of timber and turned up at 866 production units, in 1979 this volume had fallen only to 2.8 million cubic meters, affecting 777 production units. This situation is due to the low accessibility of some forests--a consequence of the still insufficient rate of equipping the forest resources with roads that would also provide for the penetration of the logging operations to the hard-to-reach forests earmarked "one after another" for cutting. It should be mentioned that, within the volume of cutting achieved, the timber coming from wind- and snow-toppled trees has been gathered with priority, there being reduced accordingly the cutting of timber "on its feet," in order to observe the planned annual quota of cutting and the good management of forests.
